An earlier ruling by a trial judge of the Court of Claims that Northern Helex Co. was entitled to $78 million in damages because the Government had breached its helium purchase contract with the company was reversed by the full U.S. Court of Claims in October 1975. The full court reduced the award to $35 million and remanded the case to the trial judge for consideration of possible further reductions.

At yearend 1975, litigation was still pending with respect to claims arising from the termination of helium purchase contracts with the National Helium Corp. and Cities Service Helex, Inc.

DOMESTIC PRODUCTION

A total of 12 domestic plants had the capacity to extract helium from natural gas during 1975. Ten of the plants were owned by private industry, and the other two are owned by the U.S. Government and operated by the Bureau of Mines. A new plant constructed by Western Helium Co. near Redrock, N. Mex., began helium extraction from natural gas in 1975.

Total domestic extraction of helium from natural gas during the year was 1.1 billion cubic feet, an increase of 22% compared with that in 1974. High purity helium extraction, however, increased only 7%, while that of crude helium was more than 81% higher than in 1974. Crude helium accounted for 31% of total helium extracted; about 69% was high purity helium for sale. The Bureau of Mines provided 55% of the crude helium and 25% of the high purity helium extracted. The remaining crude and high purity helium was extracted by private industry.

The construction phase of a new ionization chromograph was completed in June at the Bureau of Mines helium plant at Keyes, Okla. The new chromograph was designed for product quality analysis and has a minimum detectable limit for hydrogen in helium of less than 0.05 part per million and 0.5 part per million for other components. This new instrumentation will permit a high degree of sensitivity for quality control analysis of helium production.

CONSUMPTION AND USES

Domestic consumption of helium during 1975 was primarily for welding, research, purging and pressurizing rockets and spacecraft, maintenance of controlled atmospheres, leak detection, and cryogenics. Demand occurred principally in the Pacific and Gulf Coast States.

Sales of high purity helium in the United States increased about 5% during 1975. Bureau of Mines helium sales, which accounted for 31% of domestic sales, increased approximately 9% during the year.

Approximately 57% of the Bureau of Mines sales in 1975 were made directly to Federal agencies, which are required by law to purchase all of their major helium requirements[3] from the U.S. Department of the Interior. The Bureau of Mines f.o.b. plant price, which is set at $35 per thousand cubic feet for the purpose of financing the long-range helium conservation program, was not generally competitive with the 1975 average private f.o.b. plant price of $24 per thousand cubic feet.

Almost all of the remaining Bureau sales in 1975 were the result of purchases by Federal agencies from private distributors under General Services Administration contracts, which required the distributors to purchase equivalent quantities from the Bureau of Mines. These contracts made relatively small quantities of helium readily available to Federal installations with reduced freight charges for small purchases.

All high purity helium sold by the Bureau of Mines was shipped in gaseous form in cylinders, railroad tank cars, highway tanker trailers, and in liquid form in containerized dewars. Private industry distributors shipped helium in both gaseous and liquid forms. Much of the helium transported in liquid form was delivered by semitrailers and containerized dewars to distribution centers and regasified and compressed into small cylinders and trailers for delivery to consumers.

CONSERVATION

Helium held in the Bureau of Mines conservation storage system, which includes the conservation pipeline network as well as the Cliffside gasfield near Amarillo, Tex., increased about 1% during 1975. Of the 38,557 million cubic feet in storage at yearend, over 97% was held for the Bureau's conservation program, including that accepted under court order after March 28, 1971. The remaining amount was stored under contract for private companies.

The conservation storage system contains crude helium purchased by the Bureau of Mines under contracts entered into with four companies in 1961 and continued under court orders obtained during 1971 and 1973 by three of the companies.

RESOURCES

As of December 31, 1975, domestic measured and indicated helium resources were estimated at 233.5 billion cubic feet (in natural gas with a minimum helium content of 0.3%). These resources include measured and indicated helium reserves (minimum 0.3% helium) estimated at 103.3 and 41.8 billion cubic feet, respectively. The remaining resource base includes 38.6 billion cubic feet in the Bureau's conservation storage system and 49.8 billion cubic feet of helium in measured natural gas reserves with a helium content of less than 0.3%. About half of the domestic helium reserves are under Federal lease. Included are the Tip Top field in Wyoming, Keyes Field in Oklahoma, Cliffside in Texas, and the Church Buttes, Wyoming, field.

Most of the domestic helium reserves are located in the midcontinent region of the United States. A total of 86 gasfields in 10 States contain measured and indicated helium reserves. Five helium-bearing gasfields contain about 90% of domestic reserves. These fields are the Hugoton field in Kansas, Oklahoma, and Texas; the Tip Top field in Wyoming; the Keyes field in Oklahoma; and the West Panhandle and Cliffside fields in Texas. About 60% of the measured and indicated reserves at yearend were in currently producing fields. Approximately 13% of the helium-rich natural gas (minimum 0.3% helium) produced in 1975 was processed for helium extraction, while the helium contained in the remaining helium-rich natural gas output was dissipated incident to the consumption of the gas.

The Bureau of Mines continued its

efforts to survey and identify possible new domestic and foreign helium resources. A total of 360 natural gas samples from 21 States and 1 sample from Canada were collected and analyzed for helium content during 1975. None of the samples indicated the presence of major new deposits of helium. A preliminary study conducted in the Dineh de Keyah field in Apache County, Ariz., indicated that about 1.3 billion feet of recoverable helium may be present. Helium-containing natural gas was also studied in two reservoir formations. The natural gas in these reservoirs is not being produced because its caloric heat value is less than 50 British thermal units (Btu) per thousand cubic feet. The helium contents of the two reservoirs were determined to be 5.3% and 3.1%.

FOREIGN TRADE

Exports of high purity helium, all by private industry, increased about 12% in 1975 to 144 million cubic feet from 129 million cubic feet in 1974. A total of 76% of the exports were shipped to Europe, as follows: Belgium, 40%; the United Kingdom, 21%; France, 15%. Exports to Japan and Canada were 10% and 5%, respectively. The increase in exports to Western Europe in 1975 was attributed to the increased use of high purity helium in the exploration of oil and gas in that area, especially in the North Sea.

WORLD REVIEW

World production of helium, exclusive of the United States, was estimated at 146 million cubic feet in 1975. Canadian production was about 35 million cubic feet from a plant in Saskatchewan owned by Canadian Helium, Ltd. Production from a plant near Paris, France, was about 11 million cubic feet. The U.S.S.R. and countries of Eastern Europe produced an estimated 100 million cubic feet.

It was reported that hydrocarbons and helium were discovered at a depth of 20,843 feet in a well located on the Kola Peninsula near the Barents Sea, about 65 miles west of Murmansk, U.S.S.R. Reported plans called for deepening the wildcat to 23,830 feet.

During 1975, construction continued on a prototype helium extraction plant in Alberta Province, Canada. Plant design will utilize a diffusion technique for processing natural gas with a helium content from 0.05% to 0.70%. Full plant operation was scheduled for 1977, and completion cost was estimated to be about $300,000.

A joint venture by West German industry and Government has produced an experimental, closed-cycle helium turbine heating and generation plant, the first of its kind. The helium turbine in 1975 was undergoing further tests prior to commissioning. The venture is part of a research program to develop a nuclear, direct-cycle, helium-cooled, high-temperature electrical generation facility.

In early 1975, work and research continued on a natural gas upgrading and helium extraction plant at Odolanow, Poland. This plant is the first of its kind in Europe. Natural gas in the region has a methane content of 56% with a caloric value of about 580 Btu per thousand cubic feet, 43% nitrogen, and 0.4% helium. The nitrogen and helium are to be removed and the caloric value of the methane increased by a new process devised by Petrocarbon Developments, Ltd., of Manchester, United Kingdom. By this process, natural gas is fractionated in two, low-temperature distillation columns linked by a reboiler-reflex condenser. No heat pump cycle is used, thus resulting in a saving of energy and a reduction of machinery needs. The upgraded methane (980 Btu per thousand cubic feet) leaves the plant and enters the main transmission lines at 300 pounds per square inch without recompression. Overall hydrocarbon recovery will exceed 98%. The plant will also supply nitrogen purge gas and refrigeration for the recovery of helium. About 88% of the helium present in the natural gas is to be recovered. Full plant operation, processing approximately 6 billion cubic feet of gas per year, was scheduled for July 1976.

TECHNOLOGY

In October 1975, the U.S. Department of the Interior announced the development of a new helium "sniffer" device by the U.S. Geological Survey for detecting helium. The prospecting device is designed to measure microscopic amounts of helium gas in soils. Samples to be analyzed are obtained from a depth of 2 feet in the soil and transferred into a metal tube for analysis by the sniffer device. The Survey reported the device had been tested with good results over known geothermal resource areas containing high concentrations of helium. Also, in western Colorado and Utah, measurements indicated helium over several oil and uranium deposits. The sniffer can detect and measure helium concentrations in soil in amounts as small as 50 parts per million.

The Bureau of Mines developed an analytical procedure for determining the quantity of helium-3 in helium-4 in parts per billion range. Several university helium research laboratories in the United States and the United Kingdom had samples analyzed by the Bureau's equipment. The technique was developed as part of the Bureau's isotopically pure helium-4 project.

The use of helium as a tool in exploration for uranium is being studied by Martin-Marietta Aerospace and the U.S. Energy and Research Development Administration (ERDA). In theory, anomalous concentrations of helium produced by the radioactive decay of uranium are assumed to be associated with deep-seated uranium deposits. Plans call for testing helium and uranium by the sniffer measuring device in areas of known uranium ore bodies.

National Aeronautics and Space Administration (NASA) research had indicated a method for the conversion of fission energy directly into laser light by a nuclear-energized laser that contains helium. In the experiments, a reactor provided a neutron pulse to produce energetic fission fragments in a laser gas consisting of helium and xenon. These experiments point up the possibility of major advances in power transmission over long distances, energy conversion, and long-range communications.

Iron Ore

By F. L. Klinger[1]

World production of iron ore in 1975 was estimated at 880 million tons,[2] slightly below the level of 1974. World shipments of iron ore, however, were substantially less than in 1974 owing to a decline in demand for iron and steel. The leading producing countries continued to be the Soviet Union, Australia, the United States, and Brazil.

World exports of iron ore were estimated at approximately 375 million tons, of which an estimated 295 million tons were oceanborne. These totals were 6% less than in 1974. The leading exporting countries were Australia, Brazil, the Soviet Union, and Canada.

The reduced level of shipments resulted in large accumulations of ore stocks by several major producers, notably in Australia, Sweden, and Liberia. The relatively high level of stocks was expected to slow down production in 1976.

The major importing countries in 1975 continued to be Japan (129.6 million tons), the European Community (EC) (120 million tons), and the United States (46.7 million tons). Imports by Japan and West Germany in 1975 were 10 and 13 million tons, respectively, less than in 1974.

World output of iron ore pellets was estimated at 165 million tons in 1975. The United States continued to lead in production, with 62.5 million tons, followed by the Soviet Union (27 million tons), Canada (23.7 million tons), and Sweden and Australia with about 9 million tons each. Major additions to productive capacity were underway in the United States and Brazil, and new pelletizing plants were under construction or planned in at least 10 other countries.

Although production of prereduced ore grew slowly in 1975, direct reduction plants were under construction or contracted for in at least 10 countries.

Iron ore prices in 1975 were substantially higher than in 1974. These mainly resulted from rapidly rising costs of production and transportation. Ocean freight rates for iron ore continued to decline owing to the surplus of available ships and the decline in demand for ore, but rail and lake freight rates increased in the United States.

A major new iron mine (Mount Wright) began production in Canada during 1975, development of the Kudremukh deposits in India began, and the Sishen-Saldanha Bay project in the Republic of South Africa was nearing completion. Major investments in new mines and plants were being made in the United States and several other countries, but rising costs, as well as the depressed condition of iron ore markets, were making it difficult to find adequate financing for many proposed projects. There seemed to be little prospect of these conditions improving in 1976.

Increasing environmental controls have added significantly to the cost of iron ore mining projects, particularly in the United States. At yearend, it was uncertain whether Reserve Mining Co. would continue operations if required to shift its tailings disposal area farther north than proposed in 1974. The company had an annual production capacity of 10.7 million tons of iron ore pellets.

The Association of Iron Ore Exporting Countries (AIOEC) was formed in 1975. Member countries at yearend were Australia, Sweden, Peru, Chile, Mauritania, Venezuela, Algeria, Tunisia, Sierra Leone, and India. These countries accounted for about 26% of world production and 50% of world exports of iron ore in 1974. The long-range goal of the association appeared to be to obtain higher prices for iron ore, but the absence of orebuying nations from the group and the presence of large iron ore resources in nonmember countries was likely to inhibit such efforts.

---

[1] Physical scientist, Division of Ferrous Metals.

[2] The long ton of 2,240 pounds is the unit of weight used in this chapter, unless otherwise specified.

The Government of Peru nationalized the iron mining properties of Marcona Mining Co. on July 25, 1975. Agreement on compensation was not reached by yearend; meanwhile, exports appeared to have ceased. The Peruvian action followed nationalization of Venezuelan mines, effective January 1, 1975, and similar actions in Mauritania (late 1974) and Chile (1971).

EMPLOYMENT

Summary statistics on employment and productivity in the U.S. iron ore industry in 1975, as developed from data collected by the Mining Enforcement and Safety Administration (MESA), are shown in table 2.

The average number of persons employed (20,000) and the total hours worked (39.1 million) in 1975 were within 1% of the respective totals for 1974, but nationwide average productivity of usable ore declined about 6.5% due mainly to cutbacks in output of natural ore concentrates and direct-shipping ore from Minnesota mines and plants. In Michigan, employment and productivity increased in 1975 owing to the first full year of production at the Tilden mine, while in California, employment decreased due to curtailment of operations at the Beck mine.

The average number of persons employed in 1975 included approximately 11,000 engaged in mining and transport of crude ore, and 8,900 in beneficiation plants. Owing to variations in reporting practice, both of these figures include some repair and maintenance shop personnel. As in previous years, statistics published in table 2 do not include office workers. The number of office workers at mines and beneficiation plants in 1975 was approximately 2,600.

DOMESTIC PRODUCTION

U.S. mine production and shipments of iron ore in 1975 declined by 6.5% and 10.9%, respectively, compared with that of 1974. Shipments of ore from U.S. ports on the Great Lakes declined about 9%. The reductions were due to relatively low domestic demand for iron and steel in 1975.

Mine output of usable ore consisted about 80% of pellets and sinter, 18% of natural ore concentrates, and 2% of direct-shipping ore. Iron ore pellets made up more than 79% of the total output because production from natural ore mines, especially on the Mesabi range, was sharply reduced in 1975. Although fewer mines were active in the Southeastern and Western States during the year, production was reported from 3 additional small operations in Minnesota, so that the total number of producing mines in the United States (67) was 1 more than in 1974. The mines included 61 open pits and 6 underground operations.

Crude ore production in 1975 totaled about 215 million tons, 1% less than that of 1974. Open pit mines produced 96% of the total output, and 99% of the crude ore shipped was sent to beneficiation plants. The average iron content of all crude ore mined in 1975 was 33%, and the average iron content of all usable ore produced was 61.23%. Nationwide, the ratio of crude ore mined to usable ore produced was 2.72:1, compared with 2.57:1 in 1974. The relatively high ratio in 1975 was due to a larger proportion of taconite in total production compared with 1974.

The Lake Superior district accounted for nearly 85% of U.S. production of usable ore in 1975. Minnesota produced 65% of the national output, Michigan accounted for nearly 19%, and the remaining 16% was produced in 17 other States.

In Minnesota, construction of two new taconite mining operations and expansion of three others was well underway in 1975. Production from Hibbing Taconite Co. and the expansion project of Eveleth Taconite Co. was expected to start by the end of 1976. Production from the Minorca project of Inland Steel Co. and from expanded operations of United States Steel Corp. and the National Steel Pellet Project was expected to begin in 1977. Aggregate production capacity of new facilities for iron ore pellets will be 21 million tons annually in 1978. Early in 1975, Bethlehem Steel Corp. announced that production capacity of Hibbing Taconite Co. will be raised to 8.1 million tons annually, an increase of 2.7 million tons over the capacity originally planned. The latter expansion will be completed in 1979. Construction costs at these projects were revised upward in 1975 so that the total investment was expected to be $1 billion, an increase of $200 million over that anticipated in 1974.

While the above taconite projects will increase annual production capacity for pellets in Minnesota by nearly 24 million tons, the continuation of production by Reserve Mining Co., which has a production capacity of 10.7 million tons of pellets per year, was uncertain. Under a court order, Reserve will be required to shift its tailings disposal from Lake Superior to an onland site. The company's proposal to shift its discharge to a land site about 7 miles away from the concentrator ("Milepost 7"), at a cost of more than $240 million, had not been approved by State authorities by yearend. The State authorities suggested relocation to a more distant site, but the company said that this would increase the cost to at least $400 million, an amount which it considered prohibitive. Final decisions by the State and the company were possible in 1976.

In June 1975, the Minnesota Legislature raised the State's production tax on taconite concentrates (including pellets) by 39 cents per ton, retroactive to January 1, 1975. This more than doubled the production tax, which previously was about 36 cents per ton.

In Michigan, The Cleveland-Cliffs Iron Co. announced plans to increase production capacity for iron ore pellets at the Empire mine by 2.8 million tons annually by 1980. This will raise total output capacity of the operation to 8 million tons annually. The company was also considering expansion of the Tilden project to a production capacity of 8 million tons annually. The Tilden facility completed its first year of operation successfully in 1975.

In Alabama, production of brown ore concentrates at Russellville was suspended in September 1975 by United States Pipe and Foundry Co. The Russellville mine was the last operating iron mine in Alabama. Thirty-seven employees were affected.

In California, production of iron ore concentrate at the Beck mine in San Bernardino County was halted in late 1974 by Standard Slag Co. The concentrate had been produced since 1971 for export to Japan, at the rate of about 400,000 tons per year. In Pennsylvania, the iron ore pelletizing plant at Cornwall was reactivated in 1975 by Bethlehem Steel Corp. Feed for the plant was reportedly purchased concentrates.

CONSUMPTION

Total consumption of iron ore and agglomerates in 1975 was 17% less than in 1974. Consumption in steelmaking furnaces declined 27%, while consumption in blast furnaces was down 17%. Of total consumption, blast furnaces accounted for 98.3% and steel furnaces for 1.1%; the remaining 0.6% was used in the manufacture of cement, heavy-media materials, pigments, and other miscellaneous products. In blast furnaces, the weight ratio of iron ore and agglomerates consumed to pig iron produced was about 1.56:1 in 1975, compared with 1.57:1 in 1974.

Iron ore pellets made up 56% of all iron ore and agglomerates consumed in 1975, and 67% of all agglomerates consumed. These proportions were larger than in the previous 2 years.

Consumption statistics are shown in tables 11 and 12. In these tables, iron ore concentrate used to produce agglomerates such as pellets and sinter at mine sites is not reported as iron ore consumed; its consumption was reported only when such agglomerate was shipped to the furnace site and used (table 11). Iron ore concentrates and fines used to produce agglomerate such as sinter at iron and steelmaking plants is reported as iron ore consumed in table 12, and consumption of agglomerates from this source is included in table 11. In table 12, the difference in weight between iron ore consumed and agglomerate produced results from the elimination of moisture as well as the addition of materials such as flue dust, mill scale, lime, and coke.

STOCKS

Stocks of iron ore and agglomerates at U.S. mines, docks, and consuming plants totaled 69.1 million tons on December 31, 1975. This was an increase of 11.2 million tons or 19% compared with stocks on December 31, 1974, and was the highest yearend total since 1971. The lowest monthend level of stocks at U.S. consuming plants was 32.6 million tons in April 1975, compared with the record low of 24 million tons in April 1974. Of the 56.8 million tons on hand at U.S. docks and consuming plants at yearend, U.S. ores made up 57%, Canadian ores 17%, and other foreign ores 26%.

PRICES

Published prices for Lake Superior iron ores (delivered rail of vessel at lower lake ports) increased 6% to 7% during 1975. Prices for natural ores during the first 6 months of the year were unchanged from December 1974 levels, while the price of iron ore pellets quoted by different producers rose during the same period by 1.4% to 2.8%. In early July, prices for natural ores (basis 51.5% Fe, natural) increased by $1.22 per gross ton, and pellet prices increased 1.4 to 2.0 cents per long ton unit of contained iron, natural. The new prices, which remained in effect for the rest of the year, were as follows per long ton: Mesabi non-Bessemer, $18.50; Mesabi Bessemer, $18.65; Old Range non-Bessemer, $18.75; and manganiferous, $18.75. Iron ore pellets were 47.2 cents per long ton unit. Any increases in the cost of transportation and handling, subsequent to the announcement dates of the new prices (mostly July 3 to July 10), were to be borne by the buyer.

The average value (f.o.b. mine or concentrating plant) of usable iron ore shipped from domestic mines in 1975 was $21.41 per long ton, compared with $16.34 in 1974 and $12.84 in 1973. These values were calculated from producers' statements and approximated the commercial selling price less the cost of mine-to-market transportation.

Prices for Canadian and other foreign ores also increased in 1975, although prices under many Japanese contracts remained at levels set in late 1974. The price of Canadian (Wabush) iron ore pellets, f.o.b. vessel Pointe Noire, Quebec, was raised to 40.37 cents per unit of iron and manganese combined on January 2, 1975, and to 42.2 cents on September 29, 1975; the latter price was about 15% higher than in August 1974. The price of Quebec Cartier concentrates c.i.f. North Sea ports reportedly increased about 25% to $21.16 per metric ton in 1975.[3]

Swedish iron ore prices rose sharply in 1975. The major Swedish producers, Luossavaara-Kiirunavaara AB (LKAB) and Gränges AB, reported average increases in 1975 prices for most ore products of about 40% to 45% compared with 1974. LKAB reported increases in costs, however, of 37%. The price of Swedish high-phosphorus iron ore (Kiruna D, 60% Fe, 1.8% P), c.i.f. Rotterdam, was reported by Metallgesellschaft AG[4] at 80 Swedish kronor per metric ton on June 30, 1975, a rise of 38% from a year earlier. Under West German contracts for 1975, the f.o.b. price of Kiruna pellets (65% Fe) was equivalent to about 51 cents per metric ton unit of contained iron, and that of Kiruna B ore (about 65% Fe, 80% + 8 mesh) was equivalent to about 33 cents per metric ton unit. According to Gränges AB, prices for Liberian ores produced by the Lamco Joint Venture averaged about 45% more than in 1974.[5] The 1975 price of Nimba pellets, f.o.b. Buchanan, was about 46 cents per metric ton unit of contained iron, and for Nimba washed fines, 25.5 cents per metric ton unit.

The average price of Brazilian iron ore, 65% Fe, c.i.f. North Sea ports, was reported to be $20.10 per metric ton from January to June 1975, compared with $18.40 per metric ton (68% Fe) from July to December 1974.[6] The average f.o.b. value of Venezuelan iron ore exported to the United States, as indicated by U.S. Bureau of the Census data, was $15.63 per long ton in 1975, compared with $12.30 in 1974.

Some 1975 prices for iron ore under Japanese contracts are shown in the accompanying tabulation. All prices are free-on-board (f.o.b.), dry-long-ton (DLT) basis unless otherwise indicated:

Country, ore designation and grade	Approximate annual quantity (thousand tons)	Price
Australia:		
Whyalla pellets, 65.5% Fe	650	29.64 cents per 1% Fe.
Hamersley pellets, 63% Fe	2,200	30.0 cents per 1% Fe (effective July 1, 1975).
Savage River pellets, 66% to 67% Fe	2,000+	31.1 cents per 1% Fe.
Robe River pellets, 62.5% Fe	4,200	30.0 cents per 1% Fe.
Robe River fines, 56.5% Fe	2,600	14.2 cents per 1% Fe (effective Apr. 1, 1975).
Goldworthy sized lump, 64% Fe	3,000	22.18 cents per 1% Fe (effective Apr. 1, 1975).
Goldworthy fines, 64% Fe		18.86 cents per 1% Fe.
India:		
Chowgule pellets, 66% Fe	500	29.924 cents per 1% Fe (DMT basis).
Bailadila lump, 63% to 65% Fe (20% maximum-⅜")	6,000	$13.28 to $13.58 per DMT, f.o.b.t. Vizagapatnam.
Brazil:		
CVRD No. 3 contract, run-of-mine, 64% to 66% Fe	2,800	$13.90 per dry long ton (effective Apr. 1, 1975).
U.S.S.R.:		
Krivoi Rog fines, 55% to 57% Fe	1,000	$7.15 per DMT.
Krivoi Rog concentrates, 60% to 62% Fe		$7.95 per DMT.

DMT=dry metric ton f.o.b.t.=free on board, trimmed.

TRANSPORTATION

Iron ore shipments from U.S. ports on the Great Lakes during 1975 totaled 62.6 million tons, 9% less than in 1974. In addition, 17.6 million tons of ore was shipped during 1975 to destinations on the Great Lakes from Canadian ports, for a grand total of 80.2 million tons. Iron ore pellets made up approximately 80% of total shipments. These figures include shipments made during January, February, and March of 1975, which were an extension of the 1974 lake shipping season.

In March 1975, the first 12-month shipping season in the history of Great Lakes navigation was completed between Two Harbors, Minn., and lower lake ports. Icebreaking and other navigational aids were again used to extend the 1975 shipping season, and a second 12 month of ore shipping was achieved at Two Harbors in March 1976.

Statistics on shipments of iron ore from U.S. ports on the Great Lakes during the 1975 season (excluding shipments in early 1975 but including shipments in early 1976) are shown in the accompanying tabulation:

Port	Number of vessels loaded	Total tonnage shipped [1] (thousand long tons)	Average cargo (long tons)	Largest cargo (long tons)
Duluth, Minn	819	14,329	17,496	31,369
Taconite Harbor, Minn	377	9,979	26,469	57,404
Escanaba, Mich	502	8,949	17,827	32,648
Silver Bay, Minn	457	8,687	19,009	30,946
Two Harbors, Minn	306	8,225	26,878	53,423
Superior, Wis	322	6,423	19,949	30,313
Marquette, Mich	240	4,387	18,280	25,936
Total	3,028	60,979	XX	XX

XX Not applicable.

Statistics on receipts of iron ore at U.S. lower lake ports in 1974 are shown in the following tabulation (1975 data were not available):

Port	Thousand long tons [1]
Cleveland	13,959
Detroit	8,431
Indiana Harbor	8,292
Gary	7,496
Conneaut	6,877
South Chicago	6,550
Ashtabula	5,203
Toledo	4,872
Buffalo	4,766
Lorain	4,205
Burns Harbor	4,135
Huron	2,308
Total	77,094

[1] Rounded to nearest 1,000 tons.

Source: Lake Carriers Association, Annual Report 1975, p. 40, quoting U.S. Army Corps of Engineers, "Waterborne Commerce of the United States, 1974, Part III."

Lake freight rates for iron ore were increased January 1, 1975, as follows (per gross ton): From the head of the lakes to lower lake ports, $3.70; from Marquette, Mich., to lower lake ports, $3.05; from Escanaba, Mich., to Detroit and Lake Erie, $2.78; and from Escanaba to lower Lake Michigan ports, $2.22. These rates, which remained in effect through yearend 1975, were about 12% higher than those in effect during the last half of 1974. The additional charge for iron ore cargoes requiring more than 24 hours to unload, and for unloading at docks not capable of handling vessels of more than 23 feet draft, was unchanged at 25 cents per gross ton. Handling charges (car to vessel at upper lake ports, and rail of vessel to car or stockpile at lower lake ports) ranged from 39 cents to $1.10 per ton in 1975 and were about 15% higher than in 1974. The vessel freight rate from the Gulf of St. Lawrence to Lake Erie ports was unchanged at $1.70 per ton.

Construction of larger lake ore carriers and automation of unloading systems continued in 1975. Eight 1,000-foot self-unloading vessels, capable of carrying 59,000 gross tons of iron ore pellets at maximum draft, were under construction. The first of these carriers was expected to begin service in late 1976, three more in 1977, two in 1978, and two in 1979. Plans to build a 1,100-foot lake carrier were deferred pending authorization from the Corps of Engineers to allow passage of such vessels through the Poe lock at Sault Ste. Marie. During 1975, one self-unloading vessel with a cargo capacity of 24,000 tons of pellets was commissioned, three other vessels were lengthened to increase cargo capacity, and two vessels were converted to self-unloaders.

Burlington Northern Inc. awarded contracts to Arthur G. McKee & Co. in mid-1975 for construction of new shiploading and storage facilities for iron ore pellets at Superior, Wis. The facilities will be capable of loading 1,000-foot vessels, will have a total handling capacity of 18 million tons of pellets per year, and were planned for completion by the spring of 1977.

A disaster occurred on Lake Superior on the night of November 11, 1975. The 31,000-ton ore carrier *Edmund Fitzgerald* sank during a violent storm west of Coppermine Point, Ontario. All 29 crew members were lost.

Domestic rail freight rates for iron ore were increased in the fall of 1975. The increase for most routes was about 15% compared with rates in effect since December 1974, although the increases ranged from 7.7% (pellets from Marquette range to Escanaba, Mich.) to 21% (pellets from Nashwauk and Keewatin, Minn., to Duluth-Superior). In Ohio, Youngstown Sheet & Tube Co. was hauling iron ore pellets by truck from Ashtabula to Youngstown with a reported saving of $1 per ton compared with rail transport.

Ocean freight rates for iron ore continued to decline in 1975. The vessel freight rate from Sept-Iles, Quebec, to U.S. east coast ports (north of Hatteras) declined to $1.05 per ton in October, compared with $3.25 to $3.75 per ton earlier in the year. Rates from the Gulf of St. Lawrence to U.S. gulf coast ports dropped to $1.50–$1.75 per ton, from $3.10—$3.60. Spot fixtures reported by Metal Bulletin during 1975 indicated shipments of 60,000 to 90,000 tons from Sept-Iles and Port Cartier to West Europe, at $2.05 to $3.20 per ton, were $0.50 to $1 less than in 1974; shipments of 60,000 to 105,000 tons from Tubarão, Brazil, to West Europe were less than $4 per ton while shipments from Tubarão to Japan of 80,000 to 140,000 tons were less than $5 per ton; and shipments of 25,000 to 60,000 tons from Puerto Ordaz, Venezuela, to Western Europe were

$4 to $5 per ton. Fixtures from Tubarão to Baltimore for 48,000 to 60,000 tons were less than $4 per ton, while smaller shipments from Rio de Janeiro ranged from $8.75 per ton for 23,000 tons to Wilmington, N.C., to $6–$6.20 per ton for 30,000-ton cargoes to Contrecoeur, Quebec. From Liberia, rates of $3.20 to $3.30 per ton were indicated for shipments of 45,000 to 50,000 tons to U.S. east coast ports (north of Hatteras), and $2.30 to $3.50 per ton for shipments of 45,000 to 87,000 tons to West Europe. From Western Australia to Western Europe, rates of only $3.50 to $4.50 per ton were indicated for shipments of 125,000 to 150,000 tons ($2 to $3 less than in 1974), and $4.95 to $5.75 for shipments of 60,000 to 70,000 tons.

The largest individual cargoes of iron ore reported loaded at ocean shipping ports in 1975 were 265,302 long tons at Tubarão, Brazil; 258,000 tons at Sepetiba Bay, Brazil; 165,400 tons at Sept-Iles, Quebec; and 153,753 tons at Port Hedland, Australia. The largest cargoes continued to be unloaded at Japanese receiving ports; the largest shipment reportedly received in West Europe was 165,000 tons at Europoort in the Netherlands.

Pipeline transport of iron ore continued to increase, though slowly. A 31-mile slurry pipeline was commissioned in Mexico in 1975, and a 240-mile pipeline was under construction in Brazil. An estimated 3 million tons of iron ore concentrates were transported in slurry form in international trade in 1975.

The Suez Canal was reopened in mid-1975 after 8 years of closure. The event was not expected to have much effect on iron ore trade because of vessel size limitations (40,000 to 50,000 tons), relatively high insurance rates, and the canal's distance from most iron ore trade routes. It may prove convenient, however, for some ore shipments from India or the Republic of South Africa to Europe.

A disaster occurred in December 1975 when the Norwegian ore carrier *Berge Istra* sank in the Philippine Sea southwest of Mindanao. Of 31 crew members, only 2 survived. The vessel was carrying 188,000 tons of iron ore from Brazil to Japan.

FOREIGN TRADE

U.S. exports of iron ore in 1975 were 9% more than in 1974. Shipments to Canada accounted for all of the increase; exports to Canada in 1974 were lower than normal owing to a Canadian shipping strike in that year. Because of participation of Canadian steel companies in some new taconite mining operations in Michigan and Minnesota, exports to Canada are expected to increase during the next 5 years.

Exports to Japan declined sharply in 1975 owing to termination of the 5-year export contract between Standard Slag Co. and Nippon Steel Corp.

U.S. imports of iron ore for consumption totaled 46.7 million tons in 1975 and were the second highest on record. The principal supplying countries were Canada, with 41% of the total, followed by Venezuela (28%), Brazil (16%), and Liberia (5%). Imports from Brazil reached a record total of 7.5 million tons. Imports from Peru stopped in August, owing to nationalization of the operations of Marcona Mining Co. on July 26 and lack of agreement between the Peruvian Government and Marcona over compensation to be paid. Imports from Venezuela, where the properties of Orinoco Mining Co. and Iron Mines Co. of Venezuela had been nationalized on January 1, 1975, were 2.2 million tons less than in 1974. Compared with 1974, imports from Chile increased by 600,000 tons and imports from the Soviet Union doubled to 265,000 tons. New sources were India (164,000 tons) and the Republic of South Africa (128,000 tons).

The Philadelphia customs district continued to receive the largest share of imports (33%) with a record total of 15.3 million tons in 1975, followed by Baltimore (23%), Cleveland (12%), Mobile (9%), and Chicago (8.6%).

The average value of imported ore, f.o.b. country of origin, was $18.41 per ton in 1975 compared with $14.50 per ton in 1974. The average value of exported ore was $23.68 per ton, compared with $15.13 in 1974. The increase in average value of imports appeared to be due largely to a general increase in foreign iron ore prices, while the greater increase in average value of exports was due partly to the increased proportion of high-value pellets in 1975 exports.

World trade in iron ore in 1974 and 1975 is shown in tables 21 and 22.

WORLD REVIEW

Angola.—Cia. Mineira do Lobito reportedly suspended its mining operations in August 1975, presumably because of the civil war. Exports of iron ore in 1975, as indicated by trade data of the principal importing countries, totaled 2.6 million tons, or about half the quantity exported in 1974.

Argentina.—The Sierra Grande iron ore project, which is expected to supply 2 million tons of pellets per year for domestic consumption, was reported to be about 2 years behind schedule owing to delays in financing and equipment delivery. A 6-week strike by miners also affected the project in late 1975. Hierro Patagónico S.A. Minera (HIPASAM), the State operating company, hoped to begin "commercial production" in 1976.

Australia.—Production of iron ore in 1975 was slightly higher than in 1974, but exports declined to 79 million tons and accumulations of ore stocks were reported.

Pellet production in 1975 was estimated at 8.9 million tons, of which 8.5 million tons were exported. Production capacity for pellets was increased to 3 million tons per year by Hamersley Iron Pty. Ltd. and to 5 million tons per year by Cliffs Robe River Iron Associates.

Production capacity for iron ore was being increased by Mount Newman Mining Co. Pty. Ltd. to 40 million tons per year by July 1976. New production equipment added by the company included 13 Wabco 200-ton ore haulage trucks. The Hamersley Co. was planning to increase its productive capacity by about 6 million tons of ore per year, at a cost of $100 million, by beneficiating low-grade ("reject") materials at Mount Tom Price. The company's productive capacity in 1975, including that at the Paraburdoo mine, was about 40 million tons per year.

Plans to establish new iron ore mines in the Pilbara district of Western Australia continued to be announced in 1975, but firm completion dates for these projects were uncertain because the necessary contracts for ore sales were still being negotiated. Texasgulf Marandoo Ltd. planned to develop a mine 35 miles east of Mount Tom Price, with a production capacity of more than 10 million tons per year. Broken Hill Proprietary (BHP) announced plans to develop its Deepdale deposits, west of the Robe River development, for a production capacity of 15 million tons annually in the early 1980's. Together with previously announced plans by Goldsworthy Mining Ltd. to develop a mine between Mount Whaleback and Mount Tom Price, these projects would add at least 35 million tons of new production capacity to the Pilbara district by the early 1980's with an aggregate proposed investment of more than $1 billion.

The Hamersley Co. reported that operating costs per ton of ore produced increased 27% in 1975. During the last 3 years, unit costs have risen 70%, plant construction costs in the Pilbara district have risen almost 100%, and costs of providing and operating housing and other community facilities have risen even more steeply.[7]

The Australian Bureau of Mineral Resources was reported in 1975 to have revised estimates of iron ore reserves in Australia upward to 34 billion long tons, including about 25.8 billion tons of hematite ore containing 54% or more iron and 9.2 billion tons of limonitic ore containing 50% or more iron.[8]

Brazil.—Shipments of iron ore by Brazilian producers in 1975 were estimated at 79 million tons, including reported exports of 71 million tons. Shipments by Companhia Vale do Rio Doce (CVRD) totaled 55.7 million tons, of which 52.9 million tons was exported. About 16% of shipments and 13% of exports by CVRD were for the account of other companies. Shipments by Minerações Brasileiras Reunidas, S.A. (MBR) totaled 11.7 million tons in 1975, of which 10.4 million tons was exported. Most of the ore shipped by MBR (9.5 million tons) was produced at the recently opened Aguas Claras mine.

Shipments of iron ore pellets in 1975 by CVRD, the only producer, were 4.1 million tons, including exports of 3.7 million tons. The pellets were produced in two plants at Tubarão. At least four additional pellet plants, with a total production capacity of 12 million tons per year, were under construction at Tubarão in 1975, and two more, with a combined capacity of 8 million tons, were scheduled to be built. Total pelletizing capacity at Tubarão was thus expected to be 25 million tons annually by 1979.

---

[7] Hamersley Holdings Ltd. Annual Report, 1975. Pp. 4, 9.

[8] Mining Journal (London). Mining Annual Review, 1976. June 1976, p. 364.

In other developments, Ferteco Mineração S.A. was increasing production capacity for ore products at the Fabrica mine in Minas Gerais to 5 million tons annually. Facilities to be installed by mid-1977 include a 2.5-million-ton-per-year pelletizing plant and a high-intensity magnetic concentrator. In addition to pellets, annual output will include about 1.25 million tons each of lump ore and sinter feed. Shipments from the Fabrica mine in 1975 consisted of about 1.1 million tons of lump ore and 2 million tons of fines.

A new iron ore mine and concentrator will be built near Belo Horizonte by Samarco Mineração S.A., to produce about 10 million tons of iron ore concentrates annually for export. A 240-mile pipeline will be built to transport the concentrate to the coast at Ponta Ubu, where half of the concentrate will be pelletized before shipment. Cost of the project was estimated at $400 million. The operating company was owned 51% by S.A. Mineração da Trindade (SAMITRI) and 49% by Marcona International S.A. Mining operations were planned to begin in 1977, but a completion date for the entire project was not announced.

The feasibility of exploiting iron ore deposits at Serra dos Carajás by 1980 was still uncertain at yearend. While a group of Japanese, Spanish, and British companies was reportedly interested in purchasing 25 million tons of ore annually, financing arrangements were still being sought. Cost of the project was estimated in 1975 at $2.7 billion.

Consumption of iron ore in Brazil in 1975 was estimated at 11 million tons, including 275,000 tons in direct-reduction plants.

Canada.—Production and exports of iron ore in 1975 declined 6% and 4% respectively, compared with 1974. Exports in 1975 totaled 35.5 million tons, of which about 54% was destined for the United States, 33% for EC countries, and 11% for Japan. Imports rose to nearly 4.8 million tons, partly because of a strike which sharply reduced shipments of iron ore pellets from Wabush mines during the year, and partly because of increased shipments of pellets from U.S. mines which are partly owned by Canadian companies. Consumption of iron ore in 1975 totaled 13 million tons, of which about 84% consisted of pellets. Total output of pellets by Canadian producers in 1975 was 23.7 million tons.

Production of iron ore concentrates at Mount Wright, Quebec, began in September 1975. Shipments were expected to begin in 1976. The Mount Wright project, owned and operated by Quebec Cartier Mining Co. (QCM), will have a production capacity of over 18 million tons of concentrate per year by 1977; this can be increased to 24 million tons per year if desired. Production from Mount Wright will replace production from Lac Jeannine, Quebec, where QCM has produced about 8 million tons of concentrate per year since 1964. Ore reserves at Lac Jeannine were expected to be exhausted in 1976.

QCM continued to develop the Fire Lake iron deposits for production in 1976. Ore from Fire Lake will be processed at the Lac Jeannine concentrator. Production of concentrate was scheduled to reach 6 million tons per year in 1977. All of the concentrate will be pelletized at Port Cartier by 1978, in a plant being built by a subsidiary of Dravo Corp. The plant will produce 3 million tons per year of pellets for blast furnace feed and 3 million tons of pelletized superconcentrate for direct reduction plants. This project was authorized by the Quebec Government in 1975, and will be owned 50.1% by the Government-controlled steel company, Sidbec-Dosco Ltd., 41.67% by British Steel Corp., and 8.23% by QCM.[9]

In other developments, Iron Ore Co. of Canada resolved a number of production problems at the Sept-Iles flotation and pelletizing plants and increased output to more than 3 million tons of pellets in 1975. The plant was designed to produce 6 million tons of pellets per year, using flotation concentrates produced from Schefferville hematite ores. At Bruce Lake, Ontario, Steel Co. of Canada Ltd. began production of sponge iron from Griffith mine pellets in 1975. The reduction plant was of the SL/RN type, fueled by Alberta coal. The first shipment of metallized pellets was reported in July. At Sudbury, Ontario, the direct-reduction plant formerly operated by Falconbridge Nickel Mines Ltd. was leased by Sudbury Metals Co., a company owned by Allis Chalmers (Canada) Ltd. and National Steel Corp. The plant will be modified to use a reduction process developed by Allis Chalmers, for the production of 1,200 tons of prereduced pellets per day beginning in 1976. In Labrador, the Newfoundland Government expropriated certain mineral properties of Canadian Javelin Ltd. that included 1.29 square miles of the Julian Lake iron ore deposits near Wabush. The reason given was that the company had not proceeded with due diligence to develop mining operations. This allegation was strongly denied by the company.

---

[9] Goodman, R. J. Iron Ore. Ch. in Canadian Minerals Yearbook for 1975. Department of Energy, Mines and Resources, Ottawa, 1976.

Canadian forecasts of iron ore shipments were for 67.5 million tons in 1980 and 105 million tons in 2000; these included exports of 55.9 and 83.6 million tons, respectively.

Finland.—The Raajärvi mine was closed by Rautaruukki Oy. in April 1975, owing to exhaustion of iron ore reserves. The mine produced 62,000 tons of concentrate during the year. Production of concentrate from the Rautavaara underground mine, which will replace output from Raajärvi, was 45,000 tons in 1975; full production will begin in 1976 at the rate of 500,000 tons annually. Production of byproduct iron ore pellets from the Mustavaara mine was also expected to begin in 1976. The Mustavaara ore will be mined primarily for its vanadium content.

Gabon.—The Government contracted in 1975 for construction of the trans-Gabon railroad. Completion of the railroad, which was expected by 1982, will provide access to a number of resources including the Belinga iron deposits.

Guinea.—The feasibility study for development of the Nimba iron deposits near the Liberian border, being conducted by LKAB of Sweden, was scheduled for completion in 1976. The Nimba deposits reportedly contain about 600 million tons of material with an average iron content of more than 60%.

India.—Production of iron ore was reported to be about 16% more than in 1974, but exports rose about 4% to 22.8 million tons in 1975.

Development of the Kudremukh iron deposits near India's west coast was begun in 1975, after agreement was reached between the Indian and Iranian Governments on details of the project. Iran advanced $130 million and will provide another $500 million in long-term credits. India agreed to supply Iran with 210 million tons of ore over a period of 28 years beginning in 1980.

A subsidiary of Chowgule and Co. Ltd. continued construction of a 1.8-million-ton-per-year pelletizing plant near the port of Mormugao. Completion of the plant was scheduled for late 1977. Virtually the entire output of the plant was contracted for by Japanese buyers through March 1988. The contracted price of the pellets through 1979 was 34.5 cents per dry metric ton unit of iron, f.o.b. Mormugao, with provision for renegotiation of price every 2 years.

Ivory Coast.—Kaiser Engineers and Constructors, Inc., was conducting preconstruction engineering studies on development of low-grade iron deposits in the Mount Klahoyo region, for Pickands Mather and Co. International. Proposed facilities include a 186-mile railroad, a port, and a pelletizing plant with production capacity of 12 million tons per year. The studies were to be completed March 31, 1976.

Korea, Republic of.—Under a contract signed in October 1975, Pohang Iron and Steel Co. Ltd. will receive 15 million tons of iron ore during a 10-year period beginning in 1976. The supplier will be Mount Newman Mining Co. Pty. Ltd. of Australia.

Liberia.—Exports of iron ore in 1975 totaled about 18 million tons, 28% less than in 1974. Stockpiles of ore products at Liberian mines and ports at yearend were estimated at 8 million tons.

Bong Mining Co. planned to invest $120 million to expand production capacity to 7.5 million tons per year by mid-1977. The project includes a pelletizing plant of 2.4 million tons' annual capacity, and expansion of the concentrator. Ore shipments by the company in 1975 totaled 5.4 million tons, including 1.7 million tons of pellets.

The Liberian American-Swedish Minerals. Co. (LAMCO) planned to increase crude ore production at Mount Tokadeh to 7 million tons per year from the present level of 1.5 million tons. The company was also installing high-intensity magnetic separators and additional ball-milling capacity to its concentration plant. LAMCO produced 11.1 million tons of ore products in 1975, including about 2 million tons of pellets, but shipments (8.7 million tons) were the lowest since 1968.

LAMCO reserves of high-grade ore in the Nimba range, as of December 31, 1975, totaled about 120 million tons with an average iron content (dry basis) of 63%.[10]

Mexico.—The iron ore pelletizing plant of Consorcio Minero Peña Colorada S.A. at Manzanillo, on the west coast, began production in early 1975. Shipments of pellets totaled more than 1 million tons by yearend. Annual production capacity of the plant was 1.5 million tons. The plant receives concentrate through a 30-mile slurry pipeline from mines east of Manzanillo.

Shipments of iron ore pellets from Mexican plants in 1975 totaled more than 2.8 million tons, compared with 1.15 million tons in 1973.

Sierra Leone.—The Marampa mine operations of Sierra Leone Development Co. Ltd. were terminated at the end of October 1975. The principal owner, William Baird and Co. of the United Kingdom, said that the operation had been unprofitable for some time. The company had operated the mine since 1933.

Export shipments of iron ore from Sierra Leone totaled 1.2 million tons.

South Africa, Republic of.—Construction of the Sishen-Saldanha Bay mine, railway, and port project was nearing completion in 1975. Completion of the 530-mile railroad was expected in early 1976, and initial port facilities (for 100,000-deadweight-ton vessels) by late 1976.

Associated Manganese Mines of South Africa, Ltd. (ASSOMAN) contracted to export 3 million tons of iron ore per year to United States Steel Corp. for 15 years beginning in 1978. U.S. Steel acquired a 19% interest in ASSOMAN in 1975.

Sweden.—Production and exports of iron ore in 1975 declined by 15% and 30% respectively, compared with 1974. Exports totaled 22.7 million tons in 1975. Stocks of ore at Swedish mines increased by 5 million tons during the year; stocks at shipping ports also increased, and LKAB reported that an additional 1 million tons of ore was shipped for stockpiling at continental ports.

LKAB planned to rebuild the pelletizing plant at Kiruna to improve production and environmental controls. Changes in the Svappavaara plant were also planned. Production capacity for pellets was expected to increase by about 800,000 tons annually. LKAB produced 7.1 million tons of pellets in 1975, about 28% of total output of ore products. The company was also raising production capacity of the high-grade magnetite concentration line at Malmberget to 500,000 tons per year.

U.S.S.R.—Exports of iron ore in 1975 were 42.9 million tons, about the same as in 1974. Exports to east European countries, mostly Czechoslovakia and Poland, were estimated at about 38 million tons, and more than 4 million tons were shipped to Japan, Italy, and other western countries.

Crude iron ore production in 1975 was 464 million tons, from which 229 million tons of usable ore was produced. Average grade of usable ore was 59% Fe. The ratio of crude ore mined to usable ore produced was 2.03:1 in 1975, compared with 1.82:1 in 1970 and 1.34:1 in 1960. Pellet production in 1975 was approximately 27 million tons. Allis Chalmers Corp. expected to complete construction of the Kremenchug pellet plant in 1978. The plant will have a production capacity of 6 million tons of pellets per year.

Venezuela.—Nationalization of the mines took effect on January 1, 1975, the first year that the iron ore industry was under Government ownership. Under agreements with the former owners, Orinoco Mining Co. and Iron Mines Co. of Venezuela, the latter companies operated the facilities for the Government.

Production and exports of iron ore in 1975 declined by 6% and 17%, respectively, compared with 1974. Exports totaled 21.1 million tons; an estimated 62% went to the United States and most of the remainder went to EC countries.

---

[10] Liberian Iron Ore Ltd. Annual Report, 1975. P. 8.

Production of prereduced ore (high-iron briquets) at the Puerto Ordaz reduction plant in 1975 was 206,000 metric tons, with an average iron content of 84.7%. At Ciudad Guayana, construction of two direct-reduction plants with a total production capacity of about 700,000 metric tons per year were scheduled for completion in 1976. A third plant, with annual capacity of 400,000 metric tons per year using the Fior process, was to be completed at Matanzas in 1977. In 1975, contracts were let for six additional plants—three using the HyL process and three using the Midrex process—to be constructed at Ciudad Guayana by 1979. All of these plants will be fueled by natural gas. Total output capacity of the plants by 1979 was expected to be 5.3 million metric tons annually.

TECHNOLOGY

Technological trends in iron ore mining and beneficiation in 1975 continued along the lines of increasing the scale of mining operations; increasing size and productive capacity of mining, beneficiation, and transport equipment; improved instrumentation and use of computers, especially in mine scheduling and beneficiation process control; concentration of low-grade nonmagnetic ores by flotation and high-intensity magnetic separation; increased sizing and pelletization of ores; and increasing use of direct-reduction plants.

Evident worldwide in 1975 was the increased use of rotary drills for blastholes of 12- to 17½-inch diameter (with the larger diameters commonly used in taconite mining), of electric shovels with dipper capacities of 12 to 16 cubic yards, and of trucks with haulage capacities of more than 100 tons. Thirteen Wabco 200-ton trucks were being used for mining operations of Mt. Newman Mining Co. Pty. Ltd. in Australia; this is the only fleet of trucks of this size known to be used in iron ore mining, although a few 180-ton units have undergone production tests, and one 312-ton unit was being used at the Eagle Mountain mine in California in 1975.

Some open pit mines with production capacities for crude ore of 30 to 50 million tons annually were operating in Australia, Brazil, Canada, the United States, and probably the U.S.S.R. in 1975. The larger mines in the latter three countries produce low-grade ores of the taconite type.

Larger grinding mills were being installed. The ball mills for the expansion project of Eveleth Taconite Co., thought to be the world's largest, were 17 feet in diameter by 42 feet long. Six autogenous mills being installed at the concentrator of Hibbing Taconite Co. in late 1975 were 36 feet in diameter. The concentrator at Mount Wright, Quebec, which began production in 1975, is equipped with six 32-foot autogenous mills. The Mount Wright plant is reported to be highly automated and is divided into 90 sections for convenience of computer sequencing of starting and stopping.

Commercial production of iron ore superconcentrates was increasing. In Missouri, pellets produced in 1975 by Meramec Mining Co. at Pea Ridge averaged 67.5% Fe and 1.97% SiO_2. The use of high-intensity magnetic separators (HIMS) for production of high-grade concentrates from hematite ores was also increasing. At Itabira, Brazil, 1 million tons of specular hematite fines (—100 mesh) are being concentrated by HIMS to a product containing less than 1.5% SiO_2; the concentrate will be used in direct-reduction plants. At Port Cartier, Quebec, a plant being built to process Fire Lake concentrate for Sidbec-Dosco Ltd. will produce about 3 million tons of superconcentrate from —14-mesh spiral concentrate; pilot plant tests reportedly produced a concentrate containing 68.7% Fe and 1.45% SiO_2 with a 96.3% recovery. The Port Cartier plant will use Jones-type separators.[11] HIMS units were also being installed at the LAMCO concentrator in Liberia, to improve iron recovery and to increase the quantity of pellet feed produced.

Interest in low-silica superconcentrates was primarily in their use, after conversion to sponge iron in direct-reduction plants, as feed for electric steel furnaces and as a substitute for scrap.

Construction of many direct-reduction plants was underway or planned in 1975, mainly in fuel-rich countries. The availability of local supplies of high-grade iron ore was advantageous but not a necessary condition; in countries such as Qatar, Egypt, and Iran, reduction plants were being built which would be fed by imported ores. In countries having abundant resources of iron ore as well as natural gas, such as the U.S.S.R. and Venezuela, direct-reduction projects were larger. In Venezuela, annual production capacity for prereduced ore was expected to reach more than 5 million tons by 1979. Direct-reduction plants in North and South America produced about 2.2 million metric tons of prereduced ore in 1975, consuming an estimated 3.2 million tons of iron ore. Mexico accounted for about 40% of the total output; the United States, 24%; Canada, 16%; Brazil and Venezuela, about 10% each.

---

[11] Mining Journal (London). Mining Annual Review, 1976, p. 229.

Preheating of prereduced iron ore, using waste heat from electric arc steelmaking furnace gases, was investigated by the Bureau of Mines. It was concluded that such preheating can lower electrical energy requirements by as much as 15%.[12]

With expected shortages of natural gas and rising costs of oil, new pelletizing plants in the Lake Superior district were being equipped to burn pulverized coal as well as oil or gas. Iron ore producing companies were conducting commercial-scale tests on the utility of various coals for pellet induration. The Bureau of Mines investigated the possible use of lower grade coal or lignite from the Western United States. The Bureau found that the ash fusion temperature of coal was a limiting factor. If the ash fusion temperature is lower than the temperature required for pellet induration, ring buildup tends to occur in the kiln, and production problems ensue.[13] Low ash fusion temperatures were found in most of the western coal studied.

Beneficiation of nonmagnetic taconite from the western Mesabi range continued to be investigated by the Bureau of Mines. Methods used included selective flocculation-desliming of the pulp, followed by flotation; magnetizing roast, followed by magnetic separation and flotation; and high-intensity wet magnetic separation. Detailed petrographic studies were used to supplement the research. These investigations were continued into 1976.

Methods of chemical analysis for taconite and other iron-bearing materials were described by a Bureau publication. The methods were suitable for a high volume of samples, and where instrumental results must be verified.[14]

An electric ironmaking process developed by McDowell Wellman Engineering Co. was said to be capable of utilizing a wide variety of low-grade iron-bearing materials (including low-grade ores and tailings) and carbonaceous fuels. A mixture of iron-bearing material, carbonaceous material, and flux is ground, pelletized, and fed onto a traveling grate where partial reduction takes place before the material is fed into an electric arc furnace. The process was said to offer savings in capital and operating costs over the blast furnace, and to produce very little liquid or gaseous effluents.[15]

Total [4]	17,539	541	94,649	663	734	114,126

W Withheld to avoid disclosing individual company confidential data, included with "Undistributed."

[1] Not including pellets or other agglomerated products.

[2] Includes 58,239,910 tons of pellets produced at U.S. mines and 10,661,992 tons of foreign pellets and other agglomerates.

[3] Includes iron ore consumed in production of cement and ferroalloys, and iron ore shipped for use in manufacture of paint, ferrites, and heavy media.

[4] Data may not add to totals shown because of independent rounding.

Table 12.—Iron ore consumed in production of agglomerates at iron and steel plants in 1975, by State

(Thousand long tons)

State	Iron ore consumed [1]	Agglomerates produced
Alabama, Kentucky, Texas	2,987	3,489
California, Colorado, Utah	1,893	2,087
Ohio and West Virginia	2,032	3,340
Illinois, Indiana, Michigan	6,381	8,268
Maryland, New York, Pennsylvania	9,733	13,055
Total [2]	23,026	30,239

[1] Includes domestic and foreign ores.

[2] Data may not add to totals shown because of independent rounding.

Table 13.—Beneficiated iron ore shipped from mines in the United States [1]

(Thousand long tons and exclusive of ore containing 5% or more manganese)

Year	Beneficiated ore	Total iron ore	Proportion of beneficiated to total (percent)
1971	70,456	77,106	91.4
1972	72,011	77,884	92.5
1973	86,894	90,654	95.9
1974	79,995	84,985	94.1
1975	73,951	75,695	97.7

[1] Beneficiated by further treatment than ordinary crushing and screening. Excludes by-product ore.

Table 14.—Production of iron ore agglomerates[1] in the United States, by type
(Thousand long tons)

Type	Agglomerates produced	
	1974	1975
Sinter, nodules, cinder	[2]37,762	[3]30,825
Pellets	59,719	62,779
Total	97,481	93,604

[1] Production at mines and consuming plants.
[2] Includes 18,715,000 tons of self-fluxing sinter.
[3] Includes 14,942,000 tons of self-fluxing sinter.

Table 15.—Stocks of usable iron ore at mines[1] Dec. 31, by district
(Thousand long tons)

District	1974	1975
Lake Superior	2,878	5,851
Southeastern States	636	612
Northeastern States	5,083	5,191
Western States	808	646
Total	9,405	[2]12,299

[1] Excluding byproduct ore.
[2] Data do not add to total shown because of independent rounding.

Table 16.—Average value of usable iron ore[1] shipped from mines or beneficiating plants in the United States in 1975
(Dollars per long ton)

Type of ore	District			
	Lake Superior	Southeastern	Northeastern	Western
Direct shipping, hematite and magnetite	10.81	--	--	8.77
Concentrates, hematite and magnetite	11.27	--	W	15.52
Concentrates, limonite	--	7.11	--	16.22
Agglomerates	23.57	--	W	25.57

W Withheld to avoid disclosing individual company confidential data.
[1] F.o.b. mine or plant. Excludes byproduct ore.

Table 20.—Iron ore, iron ore concentrates, and iron ore agglomerates: World production, by country—Continued

(Thousand long tons)

Country [1]	Gross weight [2]			Metal content [3]		
	1973	1974	1975 [p]	1973	1974	1975 [p]
Oceania:						
Australia	[r] 83,488	95,161	96,109	[r] 52,856	60,201	60,693
New Zealand [16]	2,147	2,316	2,261	1,224	1,320	1,289
Total	[r] 832,343	881,244	880,364	[r] 473,091	505,738	507,101

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Cuba and North Vietnam may produce iron ore, but definitive information on output, if any, is not available.

[2] Insofar as availability of sources permits, gross weight data in this table represent the nonduplicative sum of marketable iron ore, iron ore concentrates, and iron ore agglomerates produced by each of the listed countries. Moreover, concentrate and agglomerates produced from imported ores are excluded, under the assumption that the ore from which they are produced has been credited as marketable ore in the country where it was mined.

[3] Data represent actual reported weight of contained metal or are calculated from reported metal content. Estimated figures are based on latest available iron content reported except for the following countries, for which grades are U.S. Bureau of Mines estimates; Panama, Uruguay, Albania, Denmark, East Germany, Hungary, Southern Rhodesia, the People's Republic of China, and North Korea.

[4] Gross weight and metal content of shipments of usable iron ore, dry tons, including byproduct ore.

[5] Gross weight calculated from reported iron content based on grade of 66.67% iron.

[6] Includes byproduct ore.

[7] Nickeliferous iron ore.

[8] Includes magnetite concentrate, pelletized iron oxide (from pyrite sinter) and roasted pyrite (purple ore).

[9] Includes "roasted ore," presumably pyrite sinter, not separable from available sources.

[10] Excludes iron oxide pellets produced from pyrite sinter.

[11] Includes manganiferous iron ore.

[12] For cement manufacture.

[13] Includes byproduct magnetite as follows in thousand long tons: 1973—[r] 2,958; 1974—[r] 2,859; 1975—2,872.

[14] Year beginning March 21 of that stated.

[15] Concentrates including concentrate derived from iron sand as follows in thousand long tons: 1973—274; 1974—[r] 232; 1975—174.

[16] Largely concentrates from magnetite-titanium sands.

Table 21.—Major world trade in iron ores, concentrates, and agglomerates (excluding roasted pyrite)[1] in 1974

XX Not applicable.

[1] Disparities between recorded total exports of source countries and totals of recorded imports of recipient countries from each listed source country are generally due to (1) time lag between shipment and receipt, and (2) the fact that the latter totals are incomplete, representing only the imports of the nations listed in the column heads and in footnotes 9, 10, and 11.

[2] Unless otherwise specified, data are compiled from official import statistics of listed recipient countries.

[3] Unless otherwise specified, data are from official export statistics of listed source countries.

[4] Official import statistics for Czechoslovakia, Poland, Romania, and the United Kingdom do not fully distribute total imports by country of origin, and therefore do not clearly indicate whether these nations received shipments from any of the source countries where this footnote has been entered.

[5] Exports not available. Production reported in lieu of exports as all or nearly all output is exported.

[6] Official mineral statistics publication of source country rather than official trade returns.

[7] In previous editions of this table, import figures for various recipient countries were adjusted to account for Swedish ores shipped through Narvik, Norway, and erroneously credited to Norway by such recipient countries. No such adjustment is necessary for 1974.

[8] Summation of (1) recorded exports of the following countries, with export quantity following country name in thousand long tons: Austria—1; Belgium-Luxembourg—68; Denmark—6; West Germany—5; Hong Kong—157; Italy—18; the Republic of Korea—75; Morocco—10; the Netherlands—193; New Zealand—2,200; Tunisia—518; together with (2) apparent exports (as measured by imports of trading partner countries) with apparent export quantity following country name in thousand long tons, and trading partner countries listed in parentheses: Indonesia—366 (Japanese imports only); North Korea—300 (Japanese imports only); Panama—23 (Mexican imports only); Poland—10 (West German imports only). In addition to the foregoing list of countries, Mexico, Monaco, Switzerland, the United Kingdom, and Yugoslavia recorded iron ore exports, but each of these nations individually exported less than 500 tons.

[9] Includes the following countries with recorded total imports of each following the country name in thousand long tons: Austria—2,756; Bulgaria—2,358; Denmark—less than ½ unit; Finland—1,115; East Germany—2,763; Greece—1,009; Norway—1,287; Portugal—10; Spain—5,197; Sweden—80; Switzerland—38; Yugoslavia—424.

[10] Includes the following countries with recorded total imports of each following the country name in thousand long tons: Australia—28; the Republic of Korea—1,373; Malaysia—less than ½ unit; Singapore—10; Taiwan—142.

[11] Includes the following countries with recorded total imports of each following the country name in thousand long tons: Argentina—1,181; Brazil—less than ½ unit; Mexico—37; Venezuela—less than ½ unit.

[12] Less than 500 long tons.

[13] Official export statistics of source country.

[14] Includes the following reported source countries with total quantity credited to each following the country name in thousand long tons: Belgium-Luxembourg—46; Czechoslovakia—73; Denmark—4; Finland—8; Gabon—57; West Germany—16; Greenland—10; Hong Kong—177; Indonesia—366; Iran—1; Italy—14; Japan—39; New Guinea—48; North Korea—300; the Republic of Korea—82; Morocco—356; Mozambique—139; the Netherlands—2; New Zealand—2,371; Nigeria—2; Panama—295; the People's Republic of China—less than ½ unit; Poland—1; Portugal—332; Thailand—23; Tunisia—112; the United Kingdom—less than ½ unit.

• Estimate.

[1] As reported by exporting country or by producers in exporting country.

[2] Including Argentina, Bulgaria, East Germany, Finland, Greece, Norway, the People's Republic of China, Portugal, the Republic of Korea, Sweden, Turkey, and Yugoslavia. Based partly on destinations as reported by exporting countries.

[3] Including Algeria, Hong Kong, Indonesia, Malaysia, Morocco, Mozambique, the Netherlands, North Korea, the Republic of Korea, Thailand, and Tunisia. Based largely on sources reported by importing countries.

[4] Imports reported by recipient countries total approximately 368 million tons.

Iron Oxide Pigments

By Cynthia T. Collins [1]

Production and trade in iron oxide pigments fell sharply in 1975. Following the trend in the automobile and construction markets, demand for pigments in the coatings, plastics, and other industries was greatly reduced. Sales of finished iron oxide pigments, valued at $46 million, and imports, valued at $9 million, indicated a $55 million domestic market in 1975. This was in contrast to a $77 million market in 1974. Plant expansions contributed to an adequate supply at the beginning of the year, although continued production and falling demand resulted in large inventories. Plants operated below capacity for most of the year. However, when overall economic improvement in related industries occurred, demand for pigments increased. Production accelerated toward yearend but was not sufficient to offset the earlier downward trend.

The American Institute of Mining, Metallurgical, and Petroleum Engineers, Inc., published a fourth edition of *Industrial Minerals and Rocks* in 1975. The chapter, "Mineral Pigments," by Kenneth R. Hancock, gives comprehensive coverage of iron oxide pigments, including natural and synthetic pigments, their chemical and physical properties, sources, manufacturing processes, end uses, and marketing.[2]

r Revised. NA Not available. W Withheld to avoid disclosing individual company confidential data.

DOMESTIC PRODUCTION

Production of finished iron oxide pigments in 1975, as measured by sales, declined 29% from that of 1974. The decline was greater for synthetic than for natural pigments. The corresponding 24% decrease in value of total shipments reflected higher unit values for synthetic pigments. Average value of synthetic pigments rose 17% from $0.303 per pound in 1974 to $0.355 in 1975, and was more than 4 times the average unit value of natural oxides.

Response to the Bureau of Mines canvass for data on finished iron oxide pigments increased in 1975. Twenty-one companies reported shipments from 27 plants in 13 States. Pfizer Inc. and Reichard-Coulston, Inc. were the largest producers of both synthetic and natural oxides. Cities Service Co., Columbian Div., was also a leading synthetics producer, while the Prince Manufacturing Co., Delta Color & Supply Co., and Blue Ridge Talc Co., Inc., were significant producers of finished natural pigments. Ten producers accounted for 95% of the 1975 sales of all finished pigments.

Production of crude iron oxide pigments also declined in 1975. Shipments and values were less than they were in 1974, but the 1975 average unit value of $0.016 was a 23% increase over that of 1974. Crude reds, yellows, blacks, and browns were produced variously by the four companies listed in table 3. Hoover Color Corp. and New Riverside Ochre Co. produced both crude and finished pigments.

Four steel companies reported production of 19,252 tons of iron oxides as a byproduct from steel plant dusts or regenerated pickle liquor. These products were reported for the first time in 1975 and were sold principally for use in ferrite manufacture.

CONSUMPTION AND USES

Apparent domestic consumption[3] of 124,039 tons of iron oxide pigments in 1975 was a 35% decline from the 1974 level of 192,093 tons. Demand for pigments in industrial coatings, plastics, and other markets affected by the automotive and construction industries was greatly reduced during most of the year, while demand for pigments in trade sales (paints, stains, varnishes, etc.), was relatively constant throughout the year. Consumption was off in all pigments categories, except natural black magnetite, sales of which increased over 1974 levels. Reds comprised 47% of all finished-pigment sales in 1975, while yellows accounted for 23%.

Data are not collected by the Bureau of Mines on specific uses for iron oxide pigments; figures in table 2 do not necessarily reflect all sales of iron oxides used for pigments and other nonsmelting purposes. A major use of iron oxide pigments is in protective coatings for industrial and marine uses. In coating strip metal the pigments contribute protective and decorative properties to ships, automobiles, and durable goods. Natural pigments are used extensively in primers, surfacers, and top coat paints for exterior protection on barns, houses, roofs, floors, cement, and freight cars. Some interior uses are for wood stains, antiquing kits, wallpaper designs, and plastics. In the construction industry, the pigments are used to color concrete blocks and other decorative products. Synthetic oxides find uses in paints, plastics, rubber, leather, fibers, and wood-grain films. Synthetics are used also in the manufacture of ferrites for magnetic tape and ink, magnetic door latches, and various electronic devices. Because of their nontoxic nature, iron oxide pigments are also used in cosmetics, as food additives, and in paper products for food packaging. Some miscellaneous uses are for jeweler's rouge, foundry sands, and soil conditioners.

PRICES

Iron oxide pigment prices remained relatively stable throughout 1975, after large increases in 1974. Slight increases occurred in only two categories; red domestic primers increased by 3 cents per pound in April, and yellow other shades rose 10 cents per pound in November.

---

[3] Indicated by quantity of finished iron oxide pigments sold plus imports of natural and synthetic iron oxide pigments minus exports of pigment-grade iron oxides and hydroxides.

Table 4.—Prices quoted on finished iron oxide pigments, per pound, bulk shipments, as of December 31, 1975

Pigment	Low	High
Black:		
Synthetic	$0.3100	$0.3200
Micaceous	.3800	.4000
Brown:

FOREIGN TRADE

The quantity of pigment-grade iron oxides and hydroxides exported from the United States in 1975 decreased 9% to 8,780 tons, compared with exports of 9,666 tons in 1974. A corresponding decline in the value of exports reflected a 20% decrease in the average unit value of $0.144 per pound. Canada received 85% of total U.S. exports, compared with 79% in 1974.

Imports for consumption of 27,979 tons of iron oxide pigments were 48% below the 54,215 tons imported in 1974. The decrease was due to overall lower demand and the recovery by domestic industry of that portion of the market which had relied on low-grade iron oxides from Japan and some European countries during the previous 2 years. Corresponding values of imports declined 44% in 1975. Average unit values for natural and synthetic pigments increased 7% and 8% to $0.061 and $0.193, respectively.

Siennas and umbers from Cyprus comprised 68% of natural iron oxide imports, while oxides from Spain accounted for 11%. West Germany accounted for 54% of the quantity and 68% of the value of synthetic imports; Canada contributed 35% and 19%. Imports from traditional sources declined in 1975, but small quantites from the People's Republic of China and Mexico showed an increase.

TECHNOLOGY

Increasing concern about the environment and pollution control regulations have led to development of techniques for regeneration of steel plant wastes. Several processes developed for the recycling of hydrochloric acid from ferrous chloride leach liquors also recover iron oxide as a byproduct or coproduct. A developing market for these oxides has led to modifications of systems in order to produce oxides specifically for the pigment and electronics industries. The Pori, Woodall-Duckham, and Keramchemie/Lurgi processes, the Falconbridge fluid-bed hydrolyzer process and the Steel Co. of Canada, Ltd.'s spray roasting procedures were described in the January and February 1975 issues of Canadian Mining and Metallurgical Bulletin.[4] A U.S. patent describes the development of an improved gamma iron oxide for magnetic recording, from a starting base of ferrous chloride. An aqueous alkali is combined with the ferrous chloride to precipitate colloidal seed hydrous iron oxide; seed is grown under controlled conditions to an amount up to double the seed weight. The synthetic oxide, lepidocrocite, is then reduced to magnetite and oxidized to magnetic gamma ferric oxide.[5]

Increasing importance is being placed on the protection of certain objects and products against deterioration by high-energy ultraviolet (UV) radiation. Iron oxide pigments are used in all bonding systems in which long-term protection, together with light transparency, is required. Studies have been made on the use of transparent iron oxides as UV absorbers. One study found that, by comparative investigation of three tint-separable pigments in the UV and visible range, it was possible to select the most favorable pigment for a specific type of application. Those pigments studied were yellow 088 VN, orange 188 VN, and red 288 VN.[6] Because the optical and technologic properties of transparent iron oxides depend upon dispersion of the pigment in the vehicle, research was carried out on dispersion and dispersion apparatus. Some of those tested were the conventional ball mill, attrition mill, continuous agitation mill, and calender. Transparent oxides usually require prewetting; therefore, various methods and wetting agents were also tested. The most effective was found to be predispersion in the dissolver of ground iron oxide and 45% solid alkyd solution in 1:1 weight ratio; 5% to 10% butanol was used as the wetting agent, with predispersion lasting for 1 to 2 hours. It was concluded that there is no one best dispersion apparatus because each requires its own definite material formulation.[7] A process was patented for producing a heat-stable transparent yellow oxide pigment. Iron carbonyl was burnt and the combustion products rapidly chilled to give a noncrystalline amorphous pigment containing a small amount of carbon.[8]

Micaceous iron oxide (MIO) is noted for its long-lasting corrosion protection properties in paints. Industrial manufacturing techniques for synthetic MIO were developed in Japan. It was found that copperas from TiO_2 plants can be used as a raw material and byproduct sodium hydroxide, generated in the manufacturing process, can be recycled.[9] Synthetic MIO having very smooth surfaces was coated with an oxide having a high refractive index, such as TiO_2. This gave improved properties over those of synthetic MIO alone, and allowed variations of color—gold, violet, blue, and green—to be obtained as interference colors. Coating was accomplished through hydrolysis of a titanium salt solution.[10] Nacreous pigments as a satisfactory substitute for gold bronzes were made by three steps: (1) Precipitation of TiO_2 or ZrO_2 on mica flakes; (2) precipitation of ferrous hydroxide onto the coated mica flakes; and (3) oxidation of the deposit to convert the iron hydroxide to hematite. The hydroxide was precipitated from a ferrous salt solution.[11] By this method a range of interference colors may be produced.[12]

The iron oxides have a number of specialty nonpigment uses. Experiments were carried out using polymer particles containing iron oxides for use as filter aids. It was found that magnetization improved the performance of the filter aids and that the particles can be successfully cleaned and returned to the filter for reuse.[13] A method was developed to improve the mechanical properties of synthetic resins by incorporating fume particles from steelmaking into the resin. The particles were less than 20 micrometers in diameter and were alined magnetically during setting of the resin.[14] In Japan Santetsu Kogyo K. K. developed a low-cost emission antipollution catalyst made from reclaimed iron oxide. The catalyst reportedly removed 91% of the nitrogen oxide from automobile exhausts at 400° C and 96% at 450° C.[15] TDK Electronics Co. Ltd. made a low-cost catalyst of active alumina coated with ferrite. Tests were reported to show that nitrogen oxide content of auto emissions could be reduced to 0.17 grams per kilometer with use of this catalyst.[16]

The growing market for ferrites generated research into various aspects of their production. Comparative studies were made on the sintering behavior of ferrite powders produced by several methods. Ferrites produced by conventional calcining and ball mill grinding were compared with those produced by dry methods and those based on coprecipitation. Best results were obtained by freeze-and-spray drying; the product was more homogeneous and was sintered at lower temperatures or by hot-pressing.[17] Dense, spherical ferrite particles, suitable for use as the carrier in electrostatographic copiers, were prepared by making a slurry of powder mixes having the desired nickel-zinc or manganese-zinc ferrite composition. The slurry was spray-dried to give beads about 100 micrometers in diameter, which were sintered to avoid agglomeration. A deflocculent was the only additive necessary in this process.[18] In a similar procedure, the incorporation of lithium cations at 600° C prevented volatilization during sintering, and the product proved to be a significant improvement over conventionally prepared material.[19] An annotated literature survey covering major developments in the area of microwave ferrite materials and devices was published in 1975. The bibliography covers the period 1968–74.[20]

Iron and Steel

By Horace T. Reno [1]

The world steel industry produced only 713 million tons of raw steel in 1975, 9% less than the quantity produced in 1974. Among the principal producers only the centrally planned economies, the U.S.S.R., and the People's Republic of China, produced more steel in 1975 than in 1974.

The high level of domestic steel output of 1974 carried through into the first quarter of 1975, slowed only by a shortage of natural gas at some midwestern mills. By the second quarter, most domestic mills had begun to cut back, and by the end of May all were operating well below capacity. Through the remainder of the year the industry reached the May level of output in only 1 week. The steel industry produced 117 million tons of raw steel [2] and shipped 80 million tons. The rate of consumption was obscured by wide changes in consumers' and producers' inventories. Consumers' inventories at the end of the year were 3.4 million tons below the February high. Service center inventories at the end of the year were 1.3 million tons below the April high. Steel producers' stocks at the end of 1975 totaled 16.7 million tons, up 3.7 million tons from a January low of 13 million tons.

There was an imbalance between supply and demand at the end of 1974, but by the end of the first quarter of 1975, most steel mill products were readily available and by the end of the second quarter only a few foundry products were still in short supply. According to the American Iron and Steel Institute (AISI) steel mill shipments to service centers and distributors comprised 19% of the total compared with 21% in 1974. Shipments of construction and contractors products comprised 16% of the total compared with 17% in 1974. Shipments to the transportation industries; automotive, rail, marine, and air, comprised 25% of the total compared with only 22% in 1974. Shipments to other markets were essentially unchanged from the proportions shipped in 1974.

Environmental control and noise abatement received much attention during the year. Steel companies operating on the shores of Lake Michigan, in a court settlement, agreed to install water recycling equipment and to stop dumping sludge and solid waste into the Indiana Harbor ship canal. Following air pollution control controversies, several steel companies closed down open hearth steelmaking furnaces rather than expend the funds necessary to control emissions. The Department of Labor held public hearings on its plan to limit noise level at industrial plants. About the same time, the Occupational Health and Safety Administration proposed to continue a 90-decibel limit on noise, but officials of the Environmental Protection Agency, strongly supported by organized labor, demanded a lower limit of 85 decibels. The regulations were not changed during the year. The AISI released a comprehensive study of the total capital requirements for the iron and steel industry to meet pollution control replacements and expansion costs.[3] The pollution costs estimated at $4.1 billion through 1977 were in agreement with most private studies.

According to AISI, the steel industry had an average of 433,800 employees in 1975 compared with an average of 512,400 in 1974. Wages averaged $10.59 per hour in 1975, compared with an average of $9.08 in 1974. The International Labor Organization Iron and Steel Committee, at its ninth session in Geneva, September 16–26, reviewed the relationship of increasing productivity in the steel industry to increasing output of iron and steel and its basic contribution to rising living standards.[4] Increased labor productivity had not offset higher employment costs in all instances. The second largest steel producer in the United States began to phase out all its steel fabricating facilities contending that costs in its shops were substantially higher than those prevailing in plants outside the industry.[5]

---

[1] Physical scientist, Division of Ferrous Metals.

[2] The term raw steel, as used by the American Iron and Steel Institute, includes ingots, steel castings, and continuously cast steel. It corresponds to the term crude steel as used by the United Nations.

[3] Arthur D. Little, Inc. Steel and the Environment. A Cost Impact Analysis. A report to the American Iron and Steel Institute. May 1975. 334 pp.

Civil rights controversies apparently were ended in the iron and steel industry when nine steel companies set up a $31 million fund to settle civil rights bias suits. The settlement was approved by the Fifth U.S. Circuit Court of Appeals on August 18, 1975.

Table 1.—Salient iron and steel statistics
(Thousand short tons)

[2] Based on average production in 1967 as 100.
[3] Defined by AISI as the capability to produce raw steel for a full order book based on the current availability of raw materials, fuels, and supplies; and of the industry's coke, iron, steelmaking, rolling and finishing facilities, recognizing current environmental and safety requirements.
[4] Data not comparable for all years.

PRODUCTION AND SHIPMENTS OF PIG IRON

Domestic production of pig iron totaled 79.7 million tons in 1975, a decrease of 15.7 million tons or 16% less than that produced in 1974. Average production of pig iron per blast-furnace-day increased to 1,837.4 tons compared with 1,735.1 in 1974 and 1,771.7 tons in 1973 according to AISI. A total of 136 furnaces were in blast at the beginning of the year, including 1 that produced ferroalloys. At yearend the total number in blast had decreased to 119 with none producing ferroalloys. There were 199 producing blast furnaces at the beginning of the year, and 196 at yearend, of which 7 were being relined and 2 were rebuilding.

Metalliferous Materials Consumed in Blast Furnaces.—For each ton of pig iron produced in 1975, an average of 1.645 tons of metalliferous materials was consumed in blast furnaces. Total net iron ore consumed in blast furnaces including agglomerates was 124.0 million tons. The total tonnage of iron ore including manganiferous ore consumed by agglomerating plants at or near the blast furnaces in producing 33.9 million tons of agglomerates was 25.9 million tons. The remainder consisted of mill scale, coke, limestone, dolomite, and small amounts of other materials. Domestic pellets charged to the blast furnaces totaled 59.4 million tons, and sinter charged was 34.7 million tons. Pellets and other agglomerates from foreign sources added an additional 11.8 million tons.

[4] I.L.O. News 75/20, Geneva, Switzerland. September 1975, 2 pp.

[5] American Metal Market. Bethlehem Steel to Phase Out All Its Fabricating Plants. V. 82, No. 171, Oct. 2, 1975, pp. 1, 20.

Blast furnace oxygen consumption totaled 25.9 billion cubic feet in 1975 according to AISI, compared with 25.8 billion cubic feet in 1974 and 21.0 billion cubic feet in 1973.

Data reported to the Bureau of Mines by the iron and steel industry showed that blast furnaces, through tuyere injection, consumed 12 billion cubic feet of natural gas, 3 billion cubic feet of coke oven gas, 295.2 million gallons of oil, 131.8 million gallons of tar, pitch, and miscellaneous fuels, and 154,205 tons of bituminous and 535 tons of anthracite coal in 1975.

PRODUCTION AND SHIPMENTS OF STEEL

The domestic steel industry produced 116.6 million tons of raw steel in 1975, 20% less than the 145.7 million tons produced in 1974. Of the total, 62% was produced by the basic oxygen process (BOP), 19% by open-hearth furnaces and 19% by electric furnaces. Shipments of steel products for the year totaled 80 million tons, 27% less than the 109.5 million tons shipped in 1974. Shipments to the automotive market totaled 15.2 million tons, 20% less than in 1974; shipments to service centers totaled 15.6 million tons, 33% less than in 1974; shipments to the construction industry were down 31%; and those to industrial and electrical machinery and equipment markets were down 24% compared with shipments to these markets in 1974.

Materials Used in Steelmaking.—Metallics charged to domestic steel furnaces in 1975, per ton of steel produced, averaged 1,281 pounds of pig iron, 1,114 pounds of scrap, and 25 pounds of iron ore, including agglomerates. In 1974, comparable quantities were 1,240 pounds of pig iron, 1,143 pounds of scrap, and 25 pounds of iron ore, including agglomerates.

According to AISI, steelmaking furnaces consumed 534,427 tons of fluorspar, 2.1 million tons of limestone, 7.1 million tons of lime, and 0.9 million tons of other fluxes. Oxygen consumption in steelmaking totaled the equivalent of 178.4 billion cubic feet compared with 212.61 billion cubic feet in 1974.

Imports of all steel products were 25% less than in 1974, but imports of alloy steels were up 8%. Exports of steel mill products were down 43% below the quantity exported in 1974.

CONSUMPTION OF PIG IRON

Pig iron consumed in 1975 totaled 76.6 million tons. In steelmaking, basic oxygen converters consumed 59.2 million tons; open hearths, 14.6 million tons; and electric furnaces, 1.0 million tons. An additional 1.8 million tons was consumed by iron foundries and miscellaneous users, principally for charging cupola furnaces. Also, approximately 3.0 million tons in the form of molten metal was used in making ingot molds and direct castings.

PRICES

Prices for steel mill products varied widely from the prices paid for steel moving in international trade. European prices were an estimated $50 per ton below those paid for domestic steel. Japanese price quotations were $25 to $30 per ton over domestic quotations and, judging by the trend in Japanese steel exports, were not discounted significantly.

Domestic prices for steel mill products on the whole were relatively stable throughout the year, but prices for selected alloys and shapes responded to market pressures. The more significant changes were in decreased quoted prices of about 10% for reinforcing bars and small angles, and increases of $20 per ton for some pipe sizes. Prices for stainless steel, sheet and strip, and some alloy steels were subjected to the greatest downward pressures.

Stabilization of domestic steel prices may have been facilitated when it was reported that buyers of foreign steel paid a $1.6 billion premium for steel products imported into the United States in 1974.[6]

Prices of iron and steel products were relatively stable in the first 9 months of the year. The composite average price of all steel products was 12.739 cents per pound at the beginning of the year, and 12.961 cents per pound at the end of the third quarter, but averaged 13.693 cents per pound in the last quarter.

The composite price for pig iron, according to Iron Age, began the year at $180.50 per short ton. It was increased to $187.67 per short ton in February and remained at that figure for the remainder of the year. The Iron Age composite price for finished steel was 12.739 cents per pound at the beginning of the year, increased to 12.928 cents per pound in February, remained unchanged through May, decreased to 12.920 cents in June, decreased to 12.912 cents in July and August, increased to 13.692 cents in September, and reached 15.693 cents per pound at the end of the year. The Iron Age average composite price for finished steel in 1975 was 13.102 cents per pound.

FOREIGN TRADE

In view of the deteriorating international iron and steel market, and wide fluctuations in selling prices, there was considerable discussion of a worldwide steel production and trade agreement by industrialists attending the International Iron and Steel Institute meeting in Mexico. The idea intrigued most of the attendees but extended discussion indicated that such a trade agreement would be impractical. U.S. producers reported that U.S. antitrust laws would not permit them to participate in such a venture, and the nine member nations of the European Coal and Steel Community rejected governmental barriers to trade in steel.

Domestic specialty steel producers were especially concerned with international trade. The Tool and Stainless Steel Industry Committee and the United Steel Workers of America, AFL-CIO, petitioned the U.S. International Trade Commission on August 5, 1975, for an investigation under section 201(b) of the Trade Act of 1974 to determine whether certain grades and shapes of stainless and alloy steels and electrical steels were being imported in the United States in such increased quantities as to be of substantial cause of serious injury or the threat thereof to the domestic industry producing like or directly competitive articles. At yearend the International Trade Commission had not yet submitted its recommendation to the President.[7]

The United States imported 12 million tons of steel mill products valued at $4.5 million in 1975, 25% less in quantity and 19% less in value than imported in 1974. Imports from the European Community countries were 36% below those in 1974, but imports from Japan were only 5% less. Total imports of carbon steel were 26% less in quantity and 10% less in value than in 1974. Imports of stainless steel were 5% less but were valued 10% higher, and imports of alloyed steel were 8% more in quantity and 44% higher in value than in 1974. Among imports of iron products and ferroalloys the widest swings were in bar iron, slabs, blooms, etc., which were 49% less in quantity and 33% less in value than in 1974.

WORLD REVIEW

NORTH AMERICA

Canada.—The Canadian iron and steel industry production pattern lagged about 3 months behind that of the United States. Steel production held up well in the first half of the year, but was down 9% to 10% in the last half. Nevertheless, the industry continued its expansion program and increased raw steel plant capacity from 18.3 to 19.6 million tons. As in the United States, the normal relationship between raw steel production and steel mill shipments was obscured by inventory adjustment. The threat of a labor strike in midyear also affected the relationship between production and shipments. The labor controversy was settled without a strike, and stocks were returned to normal levels in the last quarter.

[6] U.S. Steel News. Foreign Steel—Bargain or Boomerang? V. 40, No. 5, September-October 1975, pp. 12-14.

[7] Federal Register. International Trade Commission (TA-201-5), Stainless Steel, Alloy Tool Steel and Silicon Electrical Steel. Vol. 40, No. 155, Aug. 11, 1975, p. 33706.

Shipments of steel mill products to most markets were substantially less than in 1974, but shipments of plate were up 19% from the 1974 level, and shipments of hot rolled sheet and strip were down only 1%. Compared with 1974, shipments of rolled steel products to public and utility construction were up 16%, shipments to operating railways were up 13%, and shipments of pipes and tubes were up 13%. Canadian steel mill products were sold for $20 to $30 per ton under U.S. quoted prices. In the latter part of the year European steel was sold in Canada below domestic prices. This practice led to allegations of dumping, but at yearend the Government had not taken action.

A new 5,000-ton-per-day blast furnace at the Sault Sainte Marie works of Algoma Steel Corp., Ltd. (Algoma) was probably the most significant of the steel mill facilities completed in Canada in 1975. Among the other new facilities Algoma completed a 1,500-ton-per-day coke battery and six soaking pits; the Steel Co. of Canada, Ltd. (Stelco) completed two 75-ton electric arc furnaces, a 3-strand billet caster, and an SL/RN direct reduction plant at its Griffith mine in northwest Ontario. During the year, Stelco allocated most of its capital expenditures to the Greenfield plant at Nanticoke, Ontario. Dominion Foundries & Steel, Ltd. was installing a 5-strand 72-inch tandem cold rolling mill; Sidbec-Dosco, as part of its phase-two expansion program, was installing two 150-ton electric arc furnaces and a second Midrex reduction plant; and Atlas Steel, Div. of Rio Algom was installing one 25-ton and two 60-ton electric arc furnaces which are to replace six existing furnaces at Welland, Ontario.

There was much discussion of the possibility of a major new steelmaking facility in Nova Scotia. The Nova Scotian Government introduced legislation on February 6, 1975, to establish a Government-owned corporation to organize a new steel complex for Cape Breton. The new agency was to operate separately from the existing Sidney Steel Corp., a provincially owned company. On December 16, the premier of Nova Scotia announced that Dominion Foundries & Steel, Ltd. of Hamilton, Ontario; Estel NV Hoesch-Hoogovens of the Netherlands; National Steel Corp. of Pittsburgh, Pa.; and Thyssen International of West Germany were to assist the Province in conducting feasibility studies for a major steel complex in Cape Breton.[8]

The Steel Company of Canada Ltd. SL/RN processing unit at the Griffith mine in Ontario was fired in July 1975, and was the second SL/RN process plant in Canada. The first operated by Falconbridge Nickel Mines Ltd. was abandoned in December 1972 after achieving only 14% of design capacity. The new Stelco plant did not operate a sufficient time in 1975 to evaluate its performance.

The major steel producers of Canada promoted research to reduce Canadian dependence on high-quality metallurgical coal by actively exploring various formed coke processes.

Mexico.—The International Iron and Steel Institute annual conference was held October 13–15 in Mexico City. Steel executives from 31 countries discussed the world's steel markets, energy, economic developments, and the coal industry.

There were no significant changes in the iron and steel production and demand patterns in Mexico in 1975. The industry produced 5.8 million tons of raw steel, only slightly more than in 1974. The Mexican Government has been encouraging expansion of the domestic iron and steel industry. Late in 1974, it authorized accelerated depreciation for the industry.[9]

The Government rejected foreign participation in the Las Truchas steel project. The project will be continued from Mexico's own resources and loans from the World Bank of the United Nations and the Interamerican Development Bank.[10]

A labor strike closed the Fundidora de Monterrey steel plant for the last 2 weeks of the year. The strike was not solved at yearend.

International Finance Corp., a subsidiary of the World Bank, granted a 150-million-peso credit to Mexico's new stainless steel company, Mexinox S.A. The

[10] American Metal Market. Foreign Participation in Mexico's Las Truchas Steel Project Rejected. V. 82, No. 103, May 28, 1975, p. 6.

World Bank will also take a 45-million-peso equity position in the company. Mexinox plans a 40-thousand-ton annual capacity stainless steel plant in the industrial park at San Luis Potosi.[11]

SOUTH AMERICA

The annual meeting of the Latin American Iron and Steel Conference was held in Lima, Peru, September 22–26. The principal discussion was of plans to increase Latin American steelmaking capacity and work to become self-sufficient in raw materials. There was a great deal of interest in reports on methods to use the low-ranked coals of South America to cut down on imports of high-grade coking coals. Officials were also concerned with the limited supply of iron and steel scrap in South America.

Argentina.—The Argentina steel industry produced 2,428,000 tons of raw steel in 1975 compared with 2,595,000 tons produced in 1974. Acindar Industria Argentina S.A., the private Argentinian steel company, was authorized to build a new steel works at Villa Constitucion in the Province of Santa Fe. The plant will have an anticipated annual capacity of 600,000 tons of raw steel.[12]

Bolivia.—A study to determine the economic feasibility of an iron and steel plant industrial complex was underway in Bolivia but progress had not been reported at yearend.

Brazil.—Industrial activity was about level throughout the year and held up well in comparison with activity in the market-economy industrialized countries of the world.

The slowdown in steelmaking operations around the world apparently benefited Brazilian steel industry. Brazilian steel mills were able to buy all the metallurgical coal that they needed. The industry produced 9,158,000 tons, 11% more than the 8,270,000 tons produced in 1974. Direct reduction plants produced 234,000 tons of sponge iron in comparison with the 155,000 tons produced in 1974.

Despite the need for steel products to support its manufacturing industries, the Brazilian Government imposed restrictive import measures on pig and cast iron, ferroalloys, sponge iron, steel, ingots, and most steel mill shapes.[13]

SIDERBRAS S.A., the Government holding company formed in 1973 as an investment and administrative agent for the Conselho Consultivo da Industria Nacional de Siderúrgica (CONSIDER), reported that the Romanian Government had extended a $150-million credit for steelmaking equipment, for which the purchase of rolling mills for railmaking by Cia. Siderúrgica Nacional (CSN) would be outside Brazil's Stage III expansion program. SIDERBRAS also reported commitments for financing its Stage III expansion program from France of 750 million francs; the United Kingdom, £50 million; West Germany, $100 million; and Japan, about $200 million. The above mentioned countries agreed to 10-year financing, covering 85% of equipment purchases. Commitments for loans of 12 years, covering 90% of purchases, were obtained from Austria, $150 million, and Finland and Spain, although the amounts were not stated.[14]

The Midrex Corp. of the United States announced that it had agreed with Usinas Siderúrgicas de Minas Gerais, S.A. (USIMINAS) to construct two 400,000-ton-per-year Midrex direct reduction modules at Ipatinga, Minas Gerais.[15]

Venezuela.—The Venezuelan iron and steel industry apparently was on the threshold of a multibillion dollar expansion program that could increase its production capacity from the present 1.2 million tons per year to 4.5 million tons per year by 1980, and projected to 15 million tons per year in about 10 years. Nationalization of its iron mines and large profits accumulated from its petroleum producing industry were responsible for this optimistic outlook. Rapid industrialization has caused iron and steel demand to increase faster than the country's ability to produce steel. The excess demand has been met by imports, so a large market for domestically produced steel mill products exists. Moreover, the iron and steel industry provides an investment opportunity from which relatively rapid returns can be expected because the basic technology is already employed. Thus, steel is more attractive to the Government than petroleum byproducts for which a market would have to be developed and the technical know-how would have to be developed.

[13] National Foreign Trade Council. Resolution No. 98. Rio de Janeiro. Mar. 19, 1975, 1 p.

[14] U.S. Embassy, Brasilia. State Department Airgram A-104, June 13, 1975, 4 pp.

[15] Skillings' Mining Review. Usiminas to Construct Two Midrex Direct Reduction Plants. V. 64, No. 38, Sept. 20, 1975, p. 10.

Government-financed steel mill expansion was to be principally at the existing national steel plant at Matanzas in Guayana. This plant is administered through the CVG-Siderúrgica del Orinoco S.A. (CVG-SIDOR). The CVG-SIDOR current expansion Plan Four is scheduled to increase the corporation's raw steelmaking capacity at Matanzas to around 5.3 million tons per year. Plant capacity to produce semifinished and finished steel products is to be increased in response to predicted domestic and export demand. As part of this expansion, a contract was signed early in 1975 with VÖEST-Alpine A.G. of Austria to begin constructing pelletizing facilities to produce feed for two pilot reduction units currently under construction.

Venezuela's private sector steel industry was also planning significant major expansion projects. Of the less than 20 leading private industry steel companies, at least 9 have had major expansion projects approved by the National Steel Council (Consejo Siderurgico Nacional) since the council was created by presidential decree April 28, 1974. Among the largest, Siderúrgica Venezolana S.A. (SIVENSA) was involved in a three-stage expansion program to give it a greater degree of vertical integration, and Siderúrgica del Turbio, S.A. (SIDETUR), received approval in March 1975 for expansion of its plant in Barquisimeto to raise its annual steelmaking capacity to 100,000 tons.

The Government apparently was determined to expand local steel markets. A ruling announced by the Ministry of Development stated that by 1985 locally produced parts must account for 90% of the value of any automobile produced in Venezuela. A special provision requires that the motor and drive shaft be produced in Venezuela. The Ministry estimated that new plants required for conversion of the automotive sector would require investment of approximately 2 billion bolivars.[16]

EUROPE

The steel industries of Western European countries were the hardest hit by the worldwide economic recession of all market-economy countries. Eastern European countries, with their controlled economy, were not much affected. The European Community countries produced 138 million tons of steel and other Western European countries produced 33 million tons compared with 172 million tons and 32 million tons, respectively, produced in 1974. The Eastern European countries produced 212 million tons. Thus, the steel industry of Europe produced 383 million tons, 7% less than the 1974 record.

European Community (EC).—It was apparent early in the year that the steel industry of the EC was in trouble when the EC forward program was returned by the European Coal and Steel Consultive Committee for downward revision of the 1975 forecast. There was much discussion of possible international action to fix steel prices and cut back production; EC was under pressure to fix a floor price for steel, but resisted fixed prices though asking for production cutbacks. Community countries expressed concern about U.S. actions in petitioning for countervailing import duties and specialty alloy steel and stainless steel producers petitioning for relief under the Fair Trade Act.

Community officials followed the course of the steel industry closely, and in the last half of the year required that firms producing crude steel supply to them both their planned or estimated production and their actual production of crude steel in the form of ingots, continuous castings, and liquid steel. Estimates and forecasts were to reach the EC by the 25th of the previous month, and actual production was to reach the EC by the 5th of the following month. On June 12, the Community asked that steel production from June through September be cut back 15%.[17] Community steel output was lowest in August, but stabilized in the last months of the year at about 10 million tons per month, 3 million tons per month less than in the same period of 1974.

Under Article 54 of the European Coal and Steel Community Treaty for Safety and Hygiene Purposes, and particularly for the prevention of nuisances, the EC issued guidelines for granting industrial loans at reduced interest rates for investment in environmental control equipment.[18]

[16] U.S. Embassy, Caracas, Venezuela. State Department Airgram A-208, Nov. 11, 1975, 18 pp.

[17] U.S. Mission to the Economic Community, Brussels. State Department Telegram 5274, June 12, 1975, 2 pp.

France.—The French iron and steel industry was troubled by a low level of production, an excess labor force, and competition that in many instances forced prices below costs. The French Government led the members of the European Coal and Steel Community in pushing for international discipline in the iron and steel market, and petitioned the Community for price controls. Union Sidérurgique du Nord et de l'Est de la France S.A. (Usinor) cancelled all its 1975 investment projects and put its 40,000-man labor force on 32-hour weeks beginning October 1. Other major steel companies followed with similar actions. The industry produced 23,691,000 tons of raw steel, 20% less than the record 29,788,000 tons produced in 1974.

Germany, West.—As in other EC countries, West Germany's steel industry was plagued by a low level of production and declining prices. Moreover, low-priced steel imports cut into the industry's domestic markets and eroded many of its foreign markets. Steel for the transportation and energy markets was the exception. Prices in these markets held up well. The industry invested in capital equipment at about the same rate as in 1974. Raw steel production of 44.5 million tons was 24% less than the record output of 1974.

Italy.—Italy's iron and steel industry produced 24,070,000 tons of steel mill products in 1975, 8% less than the 26,238,000 tons produced in 1974. ITALSIDER, S.p.A. announced a $300,000,000 modernization expansion plan for its Cornigleano complex at Genoa. The Cornigleano plant is the oldest of the ITALSIDER group and one of the principal bases of the Genoa economy. It has been a source of air and water pollution in the Genoa harbor area. As the expansion program includes water treatment and smoke abatement facilities, Genoa's environmental problems should be lessened.[19]

United Kingdom.—Operation of the British steel industry and marketing of its product in 1975 emphasized that the industry is composed of two quite dissimilar parts, the public sector and the private sector. The public sector operated at a large loss and experienced trouble in holding its markets and in producing quality steel to supply all of its customers. The private sector operated profitably, maintained its markets, and in some instances was able to capture new markets by providing fast reliable service. Steel production in 1975 was 22,267,000 tons, 10% less than the restricted output of 24,720,000 tons in 1974.

British Steel Corp. (BSC), wholly owned by the Government, was the operating arm of the steel industry public sector. BSC lost more than $300 million in 1975, and carried an excess labor force of many thousands of workers through the year. Although it has been able to reduce its work force from 260,000 in 1967 to 218,000 in 1975, its labor troubles have increased progressively from 162 worker disputes in 1971 to an estimated 404 disputes in 1975. The corporation planned to lay off 20,000 workers early in 1975, but agreed to a 10,000-worker layoff following labor union objections and after the unions agreed to certain other cost-saving measures. BSC encountered strong price competition in its foreign markets and cut export prices to meet the competition. Inability to supply the domestic market completely forced the corporation to buy foreign steel to maintain its past position. However, labor and financial troubles did not affect BSC's long-term modernization and expansion plans. Its capital expenditures continued at about £300 million per year. The large steel complex at Scunthorpe was basically completed and the steel plants at Ravenscraig and Llanwern were almost completed. A start was made in expanding the plant at Redcar but only in support of the operations at Lackenby. BSC commissioned a 360,000-ton-per-year electric arc furnace steel works at Clydesdale replacing all the open hearths. It commissioned a 400,000-ton-per-year bar mill at Thrybergh and a 5,000-ton-per-day blast furnace at Llanwern. The blast furnace at Llanwern was commissioned, but it was not lit because of labor troubles there. The corporation expended an estimated £15 million for air pollution control equipment in addition to the pollution control facilities constructed coincident with new facilities.

Most BSC research and development in the environmental field was directed to noise control and better lighting. In other research, physical testing dominated. Principal among its development projects the corporation planned an £11 million formed-coke pilot plant at its Normandy Park Works.[20]

[18] European Community, Brussels. State Department Airgram ECA-46, Feb. 3, 1975, 3 pp.

[19] The Financial Times, London. ITALSIDER Expansion. Oct. 10, 1975, p. 22.

The private sector operated profitably throughout the year and produced about one-sixth of the total 22 million tons of steel produced in the United Kingdom in 1975. Reportedly, the private sector was able to maintain its markets because of its ability to respond quickly to customers' orders and its flexibility in changing from one type of product to another. Private sector matters for consideration, in addition to the much discussed joint financing of a direct reduction plant, included the possibility of raw materials joint purchase which, if purchased individually, would be in quantities too small to obtain discount prices.

In the specialty and stainless part of the steel industry the private and public sectors were not as far apart. All specialty steel producers wanted to curb imports and both the public and private sector saw the stainless steel market as having great potential for expansion because stainless steel per capita consumption in the United Kingdom was only half that of the United States, West Germany, France, and Italy. The corporation planned expenditures of £100 million for stainless steel plants and some companies in the private sector were equally active.

Western Europe.—*Austria.*—Austria's iron and steel industry, operating at about 70% of capacity, produced 4,484,000 tons of raw steel in 1975, 13% less than the 5,179,000 tons produced in 1974. The industry maintained its full labor force but cut back the working time to 3 to 4 days per week.

In some instances workers were kept on the payroll through a training program in which the full wages were paid workers for each day in training. Domestic prices for steel were increased moderately. Most steel exported went to West Germany where, under a special agreement with the EC, steel sold for consumption in the community countries could not be priced above the level of Austrian domestic prices.

To improve the competitive position of Austria's specialty steel manufacturers in foreign markets, the Austrian cabinet approved retroactively to January 1, 1975, consolidation of the country's three specialty steel producers, Gebrüder Böhler & Co. A.G., Schoeller-Bleckmann Stahlwerke A.G., and Steirische Gussstahlwerke A.G., into a new company named Vereinigte Edelstahlwerke A.G. (VEW).[21]

Portugal.—In April the Portuguese Government nationalized Siderúrgia Nacional Sarl, the only integrated steel company in Portugal. Portugal's two other steel companies, Cia. Portuguesa de Fornos Eléctricos (Electrofornos) and F. Ramada Aços e Industrias, were not affected.[22]

Spain.—Spain's steel industry produced 12,663,000 tons of steel in 1975, only slightly less than the 12,838,000 it produced in 1974. Spain was able to keep its steel mills operating by exporting to other countries, but the general low level of its own economy and that of its customers prevented rapid expansion as visualized in the 1974 plan. However, Echevarría S.A. and Tubacex, among several small steel companies, submitted expansion plans to the Ministry of Industry as part of the 1974 concerted action scheme. There was a great deal of resentment among the EC countries of Spanish steel marketing practices. It is significant that Spain's trade deficit in iron and steel products was greater in 1975 than it was in 1974.

Sweden.—Construction of the 4-million-ton-per-year integrated steel plant at Luleå was started. The Swedish Government first announced plans for this plant in 1973. At that time the estimated cost was between $500 and $600 million.[23] The Swedish steel industry produced 6,185,000 tons of raw steel in 1975, 6% less than it produced in 1974.

Yugoslavia.—The International Finance Corp., an affiliate of the World Bank, together with a group of eight banks approved a $50 million loan for major expansion of Yugoslavia's steel industry.[24]

Eastern Europe.—The Permanent Commission for the Iron and Steel Industry of the Council for Mutual Economic Assistance (CMEA), reported continuing study of means to control pollution by noxious emissions from iron and steelworks, raising of labor productivity in steel mills, development of automation of production processes and control systems, and establishment of technical specifications for such equipment. A working party of experts from CMEA countries and Yugoslavia studied the operation of refractories in the steelworks of Hungary, East Germany, the U.S.S.R., and Czechoslovakia. The experts advocated monolithic lining of casting ladles and use of the "Orbit" throwing machines manufactured in the U.S.S.R.

[24] American Metal Market. Yugoslavian Steel Plan Gets Credit. V. 82, No 182, Sept. 19, 1975, p. 8.

U.S.S.R.—The U.S.S.R. continued as the world's leading steel producer, producing 155.4 million tons of raw steel, one-fourth more than was produced in the United States in 1975. Reportedly the Midrex Corp. of the United States signed an operating license agreement with V/O Metallurgimport of the U.S.S.R. for Midrex direct reduction plants having an annual capacity of 5 million tons per year. The Midrex plants are for a proposed steelworks near Kursk on the Lebedinskiy iron ore deposit.[25]

Academicians of the U.S.S.R. Academy of Sciences recommended reorientation and expansion of the Siberian steel industry to fill reasonable proximity requirements for seamless pipe, wide strip rolled steel, and welded pipe.[26] The change recommended would enable the Siberian steel industry better to supply the steel needs visualized for the principal Siberian development projects under the 10th 5-year plan, 1976–80.

AFRICA

Libya.—The Libyan General Corp. for Iron and Steel Projects (GCISP) contracted with Dastur and Co. of India for construction of an integrated iron and steel plant at Misurata.

South Africa, Republic of.—The Government controlled South African Iron and Steel Industrial Corp. Ltd. (ISCOR) lost R35.9 million in fiscal year 1974–75. Losses were attributed to price controls, cost inflation, production difficulties, shortage of skilled staff and of coking coal, high interest on borrowed capital, and startup costs at the corporation's Newcastle mill. As a result, ISCOR revised its future expansion plans downward. Nevertheless, the major expansion program to double steelmaking capacity in the Republic of South Africa by 1980 was still in effect. The Sishen/Saldanha Bay project progressed satisfactorily. The 534 mile rail line and the Saldanha harbor works were nearly completed.[27]

ASIA

As in 1974, most Asian countries except Japan, produced more steel than in 1974. In the aggregate they produced 163 million tons of raw steel compared with 175 million tons produced in 1974.

China, People's Republic of.—Limited information from China indicates that its steel production for local consumption increased 7% over the quantity produced in 1974, and that about 10% of Chinese steel was produced in small local steelworks.

India.—In contrast to the other market-economy countries of the world, India's steel industry was booming through most of 1975. The industry produced 8,663,000 tons of raw steel, 17% more than the quantity produced in 1974. Improved labor-management relations, which led to better utilization of facilities, was the principal factor contributing to the increase. The Government of India announced a long-term wage agreement with the steelworkers which should assure that the improved relations will continue until September 1978.

The demand for steel in India did not keep pace with the increased domestic supply; nevertheless, shortages of some of the more sophisticated steel mill products continued.

There are about 100 "mini" steel mills in India. The increased rate of output in 1975, and hence profitability, did not extend to these plants. The higher costs of small inefficient operations resulted in some of the minimills going out of business.[28]

India's first sponge iron plant was inaugurated at Vijayawada, Andhra Pradesh. The plant was based on an indigenous know-how provided by India's National Metallurgical Laboratory. It was built at a cost of R10 million, adapting an old cement kiln. Reportedly, the plant produces 30,000 tons of sponge iron per year using a high-grade iron ore and nonbituminous coal.[29]

Iran.—Iranian Government plans to construct iron and steelworks to make Iran a major steel producer progressed steadily. Essentially all activity in 1975 was at the iron and steel industrial complexes at Ahwaz in the southwest, Isfahan in central Iran, and Bandar Abbas on the Persian Gulf. The only integrated steel plant among these complexes is at Isfahan. In the other areas, iron is to be produced in direct reduction plants.

Most of the work in 1975 was at Ahwaz where the Korf and Thyssen companies of West Germany and the Swindell-Dressler Co. of the United States are to build direct reduction plants.

The integrated steel plant at Isfahan was built by the Russians and is owned by the National Iranian Steel Corp. (NISC). NISC and the Soviet Union agreed to expand its annual capacity to 1.9 million tons, by late 1977 through a credit exchange.

At Bandar Abbas a feasibility study to construct a direct reduction plant and steel mill complex was completed. The complex is to be constructed by an Italian consortium.

All direct reduction plants in Iran are owned by NISC, but private industry has equity in the steelmaking and forming facilities.[30]

Japan.—Raw steel production in Japan declined for the second year in a row. The industry produced 112,782,000 tons, 13% less than it produced in 1974. All the major steelmakers raised prices as the cost of both labor and raw materials increased. U.S. coking coal was quoted at $107 per ton at the first of the year, more than twice the average 1974 cost. Japanese labor unions asked for a 29.4% wage increase but accepted 4.8% well within the 15% guideline set in consultation with the Government and in view of the Japanese economy.

According to the Japan Iron and Steel Federation, the industry's operable capacity for raw steel production in March was about 132 million tons per year. It was increased approximately 8.3 million tons during the year; therefore, the industry operated at between 80% and 85% capacity.

Japanese steel industry capital investment was up almost half over the amount invested in 1974 as construction was resumed on work postponed in 1973. There was much discussion of the possibility of the industry expanding overseas to overcome the high costs of imported energy and other raw materials, and Japanese steel officials actively sought ownership interests in foreign iron ore properties.

Japanese steelmakers, in cooperation with the Government, actively promoted research in use of nuclear energy. The Agency for Industrial Science and Technology started construction of a high-temperature heat exchanger and reducing gas generator which are to be used in a nuclear power steelmaking project. Among new steelmaking facilities, Nippon Kokan Kaisha (NKK) began construction of a steel plant on an artificial island in the Bay of Tokyo.[31] The new plant will replace NKK's Keihin steelworks, which is being phased out because of environmental problems. The new plant is expected to produce 6 million tons of crude steel per year by the end of 1978. Funabashi Steel Works, Ltd. put a new 100-ton, 70,000 kilovolt-amphere capacity electric furnace in operation on June 10.[32] Kawasaki Steel Corporation contracted with a subsidiary of United States Steel Corp. to design and build two 235-ton bottom blown oxygen steelmaking (Q-BOP) furnaces. The two Q-BOP furnaces will be the first in Japan.

OCEANIA

Australia.—The Australian steel industry produced 8.6 million tons of raw steel in 1975, only slightly more than the 8.5 million tons produced in 1974. The slight increase in relation to optimistic forecasts was attributed to a declining domestic market and the inability to meet competition in foreign markets. The domestic market decline was caused principally by depressed conditions in the building industry.

A feasibility study for a large steel mill in Western Australia was completed and distributed to members of the international consortium who authorized the work in 1974. Despite the costs escalated by inflation, the study report recognized the viability of the proposed project. Nevertheless, little progress was made in negotiations to activate the project.[33] Hoogoven's Co. of the Netherlands officially withdrew from the consortium.

[32] Iron and Steelmaker. 100-Ton Electric Furnace Started. V. 2, No. 9, September 1975, p. 7.

New Zealand.—The New Zealand Steel Ltd. plant, using a direct-reduction process to produce steel from iron sands, apparently has been operating satisfactorily. Raw steel production in 1975 totaled 204,000 tons compared with the 214,000 tons produced in 1974 and 209,000 tons produced in 1973. Sponge iron production in 1975 totaled 138,000 tons compared with 126,000 tons in 1974 and 78,000 tons in 1973. It was reported that New Zealand Steel Ltd. was in the advanced stages of planning a large expansion project much of which will be directed to increasing the capacity of the direct reduction equipment.[34]

TECHNOLOGY

Environmental matters were of great concern to industrial researchers during the year. Their most pressing problem had to do with emissions from coal coking plants at integrated steel plants and the health hazards associated with coking plant operation. Granite City Steel Div. of National Steel Corp. devised a one-spot coke receiver system which reportedly controlled atmospheric contamination during the period that finished coke was pushed from the oven.[35] The Granite City system provides full enclosure of the coke push between the coke oven and coke receiver car. A large duct connects the car with gas cleaning equipment; thus, the system does not require hand labor in the immediate proximity.

Capture of dust and fume and other emissions from iron- and steelmaking systems has been essentially perfected in the last few years, but these systems added to steel plant solid waste disposal problems. Several methods were devised in 1975 to recycle the newly generated material and, in some instances, recover most of the valuable metals contained in it. McDowell Wellman Engineering Co. of Cleveland, Ohio, developed a process to use steel mill waste products, including flue dust, mill scale, blast furnace sludge, and basic oxygen fume.[36]

The perennial search for better refining techniques and stronger corrosion resistant alloys that would retain their characteristics over a wider range of temperatures continued throughout the world. Among the more significant work reported, researchers in Europe set up a project to develop automatic, nondestructive testing which, if successful, will facilitate alloy development. Inland Steel Co. announced a process for adding lead to steel in a covered ladle rather than to the ingot in production of free machining steels.[37]

Interest in direct reduction continued unabated among those working in iron and steel research and development. Midrex Corp. experimented with the use of coke-oven gas as a substitute for natural gas in its direct reduction process.[38] Sudbury Metals, a subsidiary of Allis-Chalmers Corp. and National Steel Corp., arranged to take over the Falconbridge Nickel Mines Limited nickel-iron pellet plant which had been shut down because of less than satisfactory performance of the Lurgi metallurgical direct reduction process.[39] Sudbury Metals planned to modify the nickel plant to convert iron oxide pellets into metallized iron pellets at the rate of 1,200 tons per day.

Japanese metallurgists reported significant advances in automation and continuous operations in steelmaking at the Sixth Triennial World Congress of the International Federation of Automatic Control held in the United States at the Massachusetts Institute of Technology in August. They reported that all of Nippon Steel Corp.'s 20 blast furnaces are under partial computer control; furthermore, that only a few problems remain to be solved to achieve total automatic control of blast furnace operations.[40] Nippon Steel's Research and Development Department reported achieving dynamic control of the basic oxygen furnace at its Nagoya Works.[41] Japanese steelmakers moved closer to a continuous operation through continuous-continuous casting, fully continuous cold-rolling, continuous annealing, and fully continuous rolling of wide flange shapes.[42] The Japanese, however, lost the distinction of having the world's largest blast furnace because No. 9 furnace at Krivoy Rog in the U.S.S.R. with a working volume of 5,000 cubic meters was lit in 1974.

The metric system of measuring steel began in the United States as the United States Steel Corp. announced that it was making a variety of steel mill products available in standard metric sizes.[43]

Bureau of Mines Research.—Bureau of Mines researchers published the results of some of their work in reclaiming solid wastes associated with the iron and steel industries.[44] In experiments at the Bureau's Salt Lake City (Utah) Metallurgy Research Center treating zinc-lead dust from iron foundries, it was determined that controlled vacuum fuming of zinc to produce Prime Western zinc and a lead-rich residue was the most effective treatment. Hydrometallurgical leaching proved unsatisfactory because iron, manganese, and copper were extracted at the same time. In a study of stainless steel furnace flue dust and wastes at the Rolla Metallurgy Research Center, Rolla, Mo., a process was developed for recovering chromium, nickel, and molybdenum in a form suitable for recycling.

At the Bureau of Mines College Park Metallurgy Research Center, College Park, Md., in work to encourage recovery of iron and steel from urban wastes, Bureau of Mines metallurgists evaluated steel made from the ferrous fractions of urban refuse.[45] On a similar project it was shown that chlorination, using organic solid sources of chlorine, reduced the tin concentration in molten iron to acceptable levels.[46] Continuous charging and preheating of prereduced iron ore was described by metallurgists at the Bureau's Albany Metallurgy Research Center, Albany, Oreg.[47] As an extension of this work, the researchers demonstrated on a small scale the feasibility of melting prereduced iron ore pellets in an electric arc furnace to separate the gangue material; feeding the resulting molten metal into an electroslag furnace through a molten flux to produce an ingot of specific steel composition having the desirable properties inherent in a conventional electroslag process. Successful application of this research will advance the mechanics of steelmaking closer to a continuous process.

W Withheld to avoid disclosing individual company confidential data; included in "Total."

[1] Net ores and agglomerates equal ore plus agglomerates plus flue dust used minus flue dust recovered.

[2] Excludes home scrap produced at blast furnaces.

[3] Does not include recycled material.

[4] Fluxes consisted of the following: 6,763 limestone, 7,592 dolomite, and 520 other fluxes excluding 5,256 limestone, 15 burnt lime, 3,844 dolomite, and 288 other fluxes used in agglomerating production at or near steel plants and an unknown quantity used in making agglomerates at mines.

[5] Fluxes consisted of the following: 5,103 limestone, 6,671 dolomite, and 280 other fluxes excluding 4,309 limestone, 26 burnt lime, 3,218 dolomite, and 117 other fluxes used in agglomerating production at or near steel plants and an unknown quantity used in making agglomerates at mines.

Table 7.—Steel production in the United States, by type of furnace[1]
(Thousand short tons)

Year	Open hearth[2]	Basic oxygen converter	Electric	Total
1971	35,559	63,943	20,941	120,443
1972	34,936	74,584	23,721	133,241

1974	35,499	81,552	28,669	145,720
1975	22,161	71,801	22,680	116,642

[1] Excludes castings produced by foundries not covered by AISI.
[2] Basic and acid open-hearth production data reported separately in previous years.

Source: American Iron and Steel Institute.

Table 8.—Metalliferous materials consumed in steel furnaces[1] in the United States
(Thousand short tons)

Year	Iron ore		Agglomerates		Pig iron	Ferroalloys[2]	Iron and steel scrap

1975	92	606	553	189	74,783	1,450	65,022

r Revised.
[1] Basic oxygen converter, open-hearth, and electric furnace.
[2] Includes ferromanganese, spiegeleisen, silicomanganese, manganese metal, ferrosilicon, ferrochromium alloys, and ferromolybdenum.

Table 9.—Consumption of pig iron[1] in the United States, by type of furnace

Type of furnace or equipment	1973		1974		1975	
	Thousand short tons	Percent of total	Thousand short tons	Percent of total	Thousand short tons	Percent of total
Basic oxygen converter	68,027	69.7	66,614	71.5	59,210	77.3

Total	97,618	100.0	93,096	100.0	76,628	100.0

[1] Excludes molten pig iron used for ingot molds and direct castings.
[2] Included with "Other furnaces."
[3] Includes vacuum melting furnaces and miscellaneous melting processes.

Table 10.—Consumption of pig iron[1] in the United States, by State

(Thousand short tons)

State	1975

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Steel formed in first solid state after melting suitable for further processing or sale.

[2] In addition to the countries listed North Vietnam produces raw steel, but information is inadequate to make reliable estimates of output levels.

[3] Data from American Iron and Steel Institute (AISI). Excludes steel produced by foundries not reporting output to AISI but reported to Bureau of Census as follows (in thousand tons): 1973—1,894; 1974—[r] 2,091; 1975—1,935.

[4] Ingots only.

Iron and Steel Scrap

By D. H. Desy [1]

Reflecting general worldwide business conditions, domestic consumption of iron and steel scrap fell by 22% compared with 1974 consumption. The high scrap consumption rates of 1974 continued into the first quarter of 1975, then declined during the remaining three quarters of the year. Consumer receipts of scrap from brokers, dealers, and other outside sources in 1975 were 31% below those for 1974. Five hundred and sixteen thousand tons of direct-reduced (prereduced) iron was consumed as a substitute for scrap by steelmakers and foundries.

Legislation and Government Programs.—Several bills to amend or extend the Solid Waste Disposal Act were introduced in the Senate and House of Representatives, and a number of these were discussed in committee hearings of the House but no new legislation was passed during the year. The Senate and House of Representatives both passed bills dealing with railroad freight rates, including sections that would require the Interstate Commerce Commission to conduct an investigation of discriminatory freight rates for the transportation of recyclable or recycled materials. By yearend the Senate and House had agreed on the joint conference report.

Table 1.—Salient iron and steel scrap and pig iron statistics in the United States
(Thousand short tons and thousand dollars)

	1974	1975
Stocks Dec. 31:

Pig iron	96,792	79,638
Exports:		
Scrap (excludes rerolling material and ships, boats, and other vessels for scrapping)	8,497	9,442
Value	$823,720	$762,976
Imports for consumption:		
Scrap (includes tinplate and terneplate scrap)	201	305
Value	$27,027	$25,250

AVAILABLE SUPPLY

The new supply of iron and steel scrap available for consumption at consumers' plants in 1975 was 82.8 million tons. It consisted of 46.0 million tons of home scrap and 36.8 million tons of purchased scrap (net receipts). Compared with 1974 figures, home scrap production was down 16.7% and net receipts were down 28.0%.

---

[1] Physical scientist, Division of Ferrous Metals.

CONSUMPTION

Consumption of iron and steel scrap in 1975 was 82.3 million tons, 22.0% less than in 1974. Manufacturers of pig iron and steel ingots and castings took 62.8 million tons, or 76.3% of the total. Iron foundries and miscellaneous users consumed 16.3 million tons or 19.8%, and manufacturers of steel castings consumed the remainder.

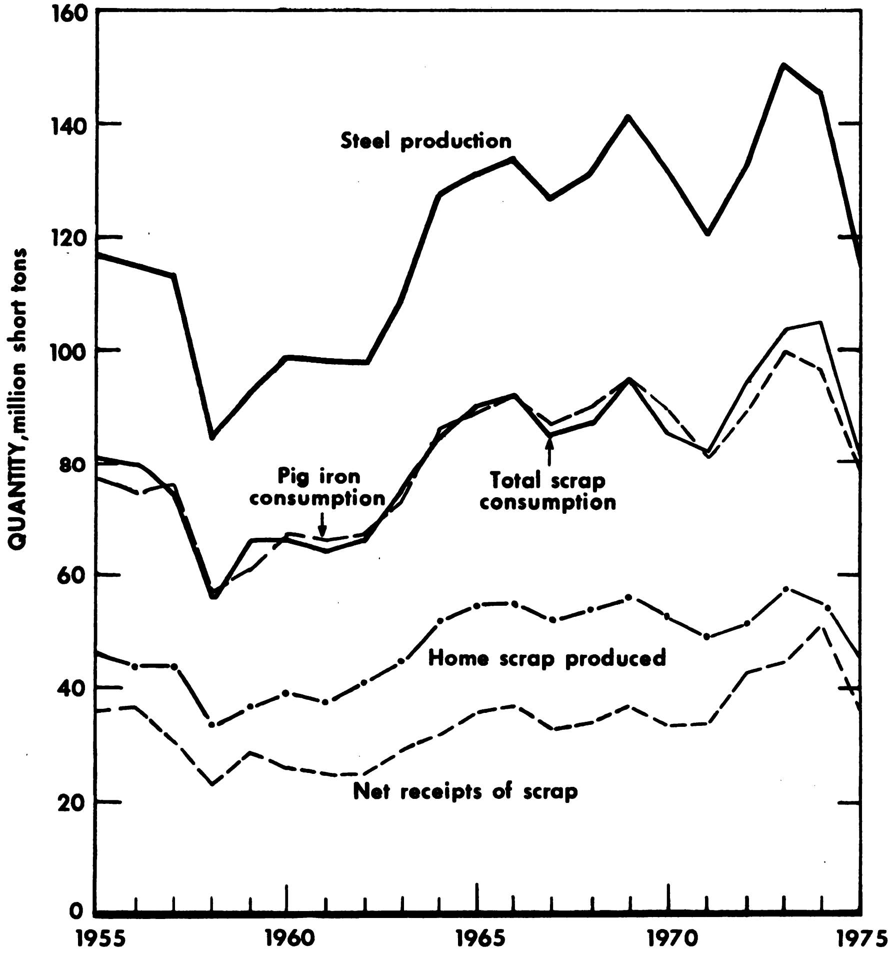

Figure 1.—Steel production (AISI), total iron and steel scrap consumption, pig iron consumption, home scrap production, and net scrap receipts.

STOCKS

Consumers' stocks reported on hand as of December 31, 1975, were 8.8 million tons, up 4.3% from 8.4 million tons at the end of 1974.

PRICES

The Iron Age composite price for No. 1 heavy melting steel scrap (Chicago, Pittsburgh, and Philadelphia) rose from $76.83 per long ton at the beginning of January to a high of $86.50 in April, declined to $58.50 in November, and rose again by yearend. The price at the end of December 1975 was $68.17, 11% below the price of $76.83 at the end of 1974.

FOREIGN TRADE

Exports of iron and steel scrap (excluding rerolling material, and ships, boats, and other vessels for scrapping) amounted to 9.4 million tons in 1975, 11.1% more than the 8.5 million tons exported in 1974.

Japan was the largest importer of U.S. scrap, taking 25.5% of the total in 1975. The next largest shares went to Spain, with 18.1%, and Mexico, with 13.4%.

No. 1 heavy melting steel scrap continued as the largest export grade, accounting for 29.3% of the total. Next largest export grades were shredded steel scrap and No. 2 bundles, which accounted for 25.5% and 12.3%, respectively.

WORLD REVIEW

Belgium.—Steel production in Belgium declined 30% from that of 1974, and this was reflected by decreases in scrap purchases and consumption. Total ferrous scrap consumption in Belgium in 1975 was 4.1 million tons, down 24.7% from the 1974 figure of 5.4 million tons. Imports (including Luxembourg) were 779,000 tons of which 769,000 tons came from European Community (EC) countries. Exports (including Luxembourg) amounted to 586,000 tons of which 525,000 tons went to EC countries. Imports and exports declined by 19% and 27% respectively, compared with 1974 figures.

Brazil.—Demand for ferrous scrap fell off in 1975, and prices paid were generally about 30% below the ceiling prices established by the Government. Brazil had excess scrap processing capacity in 1975, because of equipment bought in 1973 and 1974 in anticipation of increased steel production. Import controls on ferrous scrap were imposed by the Government for the past few years. A new organization of scrap dealers and processors was formed in May 1975, known as the National Institute of Ferrous Scrap Preparation Enterprises (INESFA), and now has 58 members in Brazil.

Canada.—Export controls on ferrous scrap were removed on January 16, 1975, but licensing of exports remained in effect. Exports in 1975 increased by 59% over those of 1974 to 463,000 tons. Exports to the United States amounted to 346,000 tons, an increase of 61% over the quantity for 1974. Imports, at 1,024,000 tons, were up 21% from those of 1974. Virtually all ferrous scrap imports came from the United States. Canada's net imports of scrap from the United States have shown a general declining trend in the past 5 years.

Czechoslovakia.—Raw steel production in 1975 was 15.8 million tons, 5% higher than in 1974, and total scrap consumption was 7.9 million tons, up 3% over 1974 consumption.

France.—Ferrous scrap consumption in 1975 declined by 20% from 1974 figures, amounting to 8.3 million tons. Imports, at 305,000 tons, were 16% less than in 1974, and exports were 25% less, amounting to 3.1 million tons. Over 95% of scrap trade was with EC nations. Of the exports to EC, 2.3 million tons, or 80% went to Italy.

Germany, West.—Reflecting the worldwide recession in the steel industry, exports of ferrous scrap amounted to 2.4 million tons, 13% less than in 1974, and imports were 1.9 million tons, 5% less than in 1974. Imports from EC countries decreased by 13% to 1.6 million tons. Decreased production by steelworks and foundries, which were 24% and 25% less than in 1974, respectively, also affected scrap consumption. The steelworks consumed 23% less scrap than in 1974. Scrap purchased by steelworks amounted to 7.9 million tons, or 20% less than in 1974, whereas foundries purchased 5% less, or 2.1 million tons.

India.—The scrap industry in India is mainly labor-intensive. Almost 80% of all scrap is handled manually from the point where it is generated to the consuming works. Scrap processing facilities in India, which handle only 20% of the scrap turnover, consist of one fragmentizer, about 15 briquetting presses, 40 to 50 mechanical and hydraulic presses, 25 to 30 turnings crushers, and a number of alligator shears. Most scrap processing equipment is based in port cities such as Bombay, Calcutta, and Madras. Heavy melting scrap is segregated by hand, sheet cuttings are tied into bundles manually, and swarf is manually sieved. Even iron and steel skull scrap is broken by hammer and chisel. Because of a shortage of processing capacity, India plans to import about 50 briquetting presses and 75 baling presses. The integrated steel plants in India make up their scrap charge requirements solely from recirculated scrap. Purchased scrap is used by electric furnace plants and rerollers. Under scrap export restrictions, only about 100,000 tons per year of lower grade scrap can be exported.

Japan.—Japan's imports of ferrous scrap declined to 3.4 million tons in 1975, 13% less than in 1974. Imports from the United States in 1975 were 2.4 million tons, 19% less than in 1974. In the second half of 1975, imports from the United States declined by 36%, compared with those of the first half year.

Spain.—Total consumption of scrap in 1975 was 7.4 million tons, 10% less than in 1974. Imports amounted to 866 million tons, of which 66% came from the United States, 25% from EC countries, and the remainder from other countries. Shipbreaking was an important source of scrap. A recent study of the capacity of Spanish shipbreaking yards gave the following estimates by area: Galicia-Asturias, 159,000 tons; Santander, 386,000 tons; Vascongadas, 231,000 tons; Cataluna, 247,000 tons; and Levante, 540,000 tons, for a total of 1,563,000 tons.

Taiwan.—Shipbreaking berths have been expanded from 12 to 48; as a result, it is expected that more scrap will be generated from shipbreaking than can be consumed domestically, and the excess will be exported.

United Kingdom.—Since attaining full membership in EC, the United Kingdom may now export and import ferrous scrap freely with other members of EC. However, exports to third countries outside EC are subject to quotas, as they are for all other members of EC. The British Steel Corporation (BSC) proposed a system for dealing with the scrap industry whereby the number of firms dealing directly with BSC would be reduced from approximately 300 to 30 or 40. Other dealers wishing to sell to BSC would be obliged to do so through one of the direct dealers. In addition to the larger dealers, several consortia of medium-sized dealers were expected to be set up to deal directly with BSC. The plan was expected to be put into effect in the spring of 1976. The BSC was building a stockpile of 1.5 million tons of ferrous scrap during 1975.

A new company was formed to recover tin and steel from tin cans recovered from municipal waste. Known as Material Recovery Ltd., the company was organized by Metal Box Ltd., the United Kingdom's leading canmaker, Batchelor Robinson and Co. Ltd., the leading detinner, and BSC. The plant will be set up at the refuse transfer station at Benwell, Newcastle-on-Tyne. After magnetic separation, the cans will be shipped to the Hartlepool plant of Batchelor Robinson where they will be cleaned and detinned. The detinned scrap will be baled and shipped to BSC. The plant could eventually yield 6,000 tons per year of scrap.

TECHNOLOGY

The number of automobile shredders in the United States continued to increase. Approximately 150 shredders were operating at yearend and about 50 others were ordered or being installed. The total amount of shredded scrap consumed domestically or exported was 5.15 million tons, 2% less than in 1974. Environmental factors influenced the operation of most shredders. Air cleaners are required to collect the light fraction of the shredded automobiles, consisting mainly of fabric, insulating material, and foamed plastic. Noise and vibration were controlled in one installation by supporting the shredder on air bags.

A few plants for the recovery and separation of the nonferrous metal fraction of automobile shredder residues were in operation during the year. To operate economically, such plants must receive residues from several shredders. It is estimated that around 20 plants would be required to handle all the residues from U.S. shredders. Some of the plants operating are using separation methods based on research conducted by the Bureau of Mines.[2]

Hot briquetting as a means of handling turnings and borings gained in importance during the year. The advantages over the cold briquetting method include a product that is denser and more durable and is free from moisture and oil.

Hydraulic cranes are rapidly gaining in popularity over the traditional cable-controlled crane. The hydraulic cranes may be equipped with grapple or electromagnet, and are particularly well suited for feeding scrap processing equipment. Among their advantages are greater speed, accuracy, and mobility, less damage caused to tracks and railroad cars, and less operator training required. Hydraulic shears and bailer-shears are also gaining in popularity. The trend is to larger machines, which can flatten and shear an entire car body.

A cryogenic method for processing whole cars, including engine, transmission, and wheels has been developed in Liège, Belgium, in the past 5 years. The automobile is bailed and cooled to liquid nitrogen temperature (−196°C) in a cooling tunnel. At this temperature, steel is embrittled so that it is easily reduced to small pieces in a fragmentizer. Rubber and plastics are also embrittled and reduced to gravel-size chips. The resulting product is separated by magnetic and density methods.

At the Bureau of Mines' Twin Cities (Minn.) Metallurgy Research Center, research is continuing on utilizing the sensible heat in the offgas produced during oxygen blowing of an experimental basic oxygen furnace to preheat the scrap to be used in the next heat of metal. Previous work had shown that up to 40% of preheated scrap could be used in the furnace charge, with a saving of up to 44% of the energy required to melt the scrap. The effects of varying the operating conditions were being determined in 1975. In another project at Twin Cities, mixtures of raw refuse scrap and shredded automobile scrap were melted in a cupola to produce gray cast iron. Cupola operation and iron quality were satisfactory with proportions of ferrous refuse scrap of up to 60%. The aluminum content of the refuse scrap tended to reduce the sulfur content of the iron and increase silicon recovery.

Research at the Bureau's College Park (Md.) Metallurgy Research Center in cooperation with the Albany (Oregon) Metallurgy Research Center and National Steel Corporation, was conducted to determine problems associated with the use of ferrous fractions from urban refuse as melting stock for steelmaking, and to evaluate the resulting steel products.[3] Fifty-pound ingots from laboratory melts and from 1-ton electric arc furnace melts were hot rolled to provide material for mechanical and corrosion testing. Most of the ingots were rolled successfully and exhibited acceptable surface and edge conditions. Tensile strengths were not significantly affected by copper content up to 0.65% or by tin content up to 0.16%. Yield strength increased with increasing copper and tin contents, and impact strength decreased with increasing tin content. In general, properties of the steel produced were not significantly affected by charge composition, melting practice, or method of scrap preparation.

The Bureau's Rolla (Mo.) Metallurgy Research Center, with the cooperation of the Twin Cities Metallurgy Research Center and Union Carbide Corp., continued their research to recover iron, chromium, nickel, manganese, and molybdenum from wastes generated by stainless steel producers. These wastes, which included argon-oxygen process dust, electric furnace dust, grinding swarf, and mill scale, were pelletized with coke breeze as a reductant and portland cement as a binder. The laboratory-scale process has been described in a Bureau publication.[4] In a 2,000-pound heat, recoveries of iron, chromium, and nickel were 89%, 81%, and 82%, respectively, and an ingot having the composition 65% iron, 14% chromium, and 6% nickel, with smaller quantities of manganese and molybdenum, was produced. This product can be recycled to the steel furnace. Some steel companies have used this process experimentally and several companies were planning to use it on a commercial basis.

r Revised. NA Not available.

[1] Not reported before 1955.

[2] Before 1942, does not include consumption for ferroalloys or miscellaneous uses.

[3] Not reported after 1952.

[4] Data may not add to totals shown because of independent rounding.

[5] Augmented reporting panel used beginning in 1974.

r Revised.

[1] Includes crucible furnace, 1958–67, and vacuum-melting furnace, 1963–67.

[2] Includes Brackelsberg furnace, 1937–51.

[3] Includes basic oxygen furnace, 1954–58.

[4] Not surveyed before 1942. Separately recorded, 1942–67, and included with other, 1968–75.

[5] Includes rerolling material and miscellaneous uses, 1942–67; includes vacuum-melting furnace and miscellaneous uses, 1968–75.

[6] Data may not add to totals shown because of independent rounding.

[7] Included with Bessemer.

[8] Included with other.

[9] Augmented reporting panel used beginning in 1974.

r Revised.

[1] Includes crucible furnace, 1958–67, and vacuum melting furnace, 1963–67.

[2] Includes Brackelsberg furnace, 1937–51.

[3] Includes basic oxygen furnace, 1954–58.

[4] Data may not add to totals shown because of independent rounding.

[5] Includes crucible and puddling furnaces.

[6] Less than ½ unit.

[7] Included with Bessemer.

[8] Included with other.

[9] Includes pig iron used for direct casting.

[10] Augmented reporting panel used beginning in 1974.

Total[6]	129,679	149,369	169,471	169,374	132,959
Grand total[6]	296,181	326,486	354,003	360,032	311,438

[e] Estimate.

[1] Unless otherwise noted, figures represent consumption of scrap in the production of pig iron, ferroalloys, crude steel, foundry products, and rerolled steel, as well as in other unspecified uses by the steel industry and by other (unspecified) industries. Also, unless otherwise noted, figures are from: United Nations Economic Commission for Europe, Annual Bulletin of Steel Statistics for Europe. V. III, 1975. New York, 1976, 97 pp.

[2] Excludes scrap consumed in rerolling.

[3] Excludes scrap consumed in foundries.

[4] Excludes scrap consumed within the steel industry for purposes other than manufacture of pig iron, ferroalloys, crude steel, and foundry products and that used in rerolling.

[5] Excludes scrap used outside the steel industry.

[6] Total of listed figures.

[7] Central Statistics Bureau. Bergshantering (Mining) 1973. Stockholm 1974, p. 105.

[8] Following United Nations' practice, Yugoslavia has been included with other market economy nations of Western Europe.

[9] Excludes scrap used in production of pig iron.

[10] Excludes scrap used in production of steel by any method of production except open hearth furnace.

[11] British Steel Corporation. International Steel Statistics, the U.S.S.R., 1973, p. 2.

[12] 1971-72: U.S. Bureau of Mines estimates; 1973-74: Latin American Iron and Steel Institute. Anuario Estadistico de la Siderurgia y Mineria del Fierro de America Latina 1974, p. 18, Santiago (undated); 1975: Latin American Iron and Steel Institute. Informativo Estadistico No. 29, Sept. 16, 1976 (not paginated). Data for 1973-74 are given in sources as total consumption by the steel industry, but no breakdown by use within that industry is provided, and sources do not make it clear whether or not consumption in foundries and rerolling plants is included; consumption other than in the steel industry is clearly excluded.

[13] Uruguay plus unspecified countries in Central America, as reported in source.

Kyanite and Related Materials

By Michael J. Potter[1]

Kyanite, andalusite, and sillimanite are anhydrous aluminum silicate minerals that are alike in both composition and use patterns and have the same chemical formula, $Al_2O_3 \cdot SiO_2$. Related materials include synthetic mullite, dumortierite, and topaz, also classified as aluminum silicates, although the last two additionally contain substantial proportions of boron and fluorine, respectively. All of these kyanite-group substances have the capability of serving as raw materials for manufacturing special high-performance refactories in the high-alumina category, but there has been no record in recent years of significant utilization of either dumortierite or topaz for this purpose in the United States.

Although published statistics are not sufficiently complete to be wholly conclusive, it appears that the United States, India, and the Republic of South Africa are the leading world producers of kyanite-group minerals. It can be presumed that the U.S.S.R. and perhaps a few other industrialized nations also produce significant quantities of these materials.

Domestic kyanite production in 1975 was somewhat lower in tonnage and value compared with 1974. U.S. exports of kyanite and related minerals have shown an increasing trend over the last several years, including 1975. U.S. imports, however, have decreased from 7,600 tons in 1955 to 65 tons in 1975.

Activities of U.S. companies included the C-E Minerals, Inc. plant expansion at Graves Mountain, Ga., and Kyanite Mining Corp.'s construction work on its third concentrating plant near Willis Mountain, Va. Ethyl Corp. continued its development program at Woodrat Mountain, Idaho.

Legislation and Government Programs.—The allowable depletion rates for kyanite, established by the Tax Reform Act of 1969 and unchanged through 1975, were 22% for domestic production and 14% for foreign operations.

The U.S. Geological Survey's Office of Minerals Exploration provides government loans of up to 50% of approved costs for the exploration of eligible kyanite deposits; no loans for that purpose were made in 1975.

DOMESTIC PRODUCTION

Kyanite was produced in 1975 at three open pit mines: Two in Virginia and one in Georgia. Kyanite Mining Corp. operated the Willis Mountain mine in Buckingham County, Va., and the Baker Mountain mine in adjoining Prince Edward County, Va. C-E Minerals, Inc., operated the Graves Mountain mine in Lincoln County, Ga.

Domestic kyanite output in 1975, as measured by the quantity sold or used, was somewhat lower in tonnage and value than in 1974. Specific kyanite production statistics for 1975 (as well as for all years since 1949) are withheld to avoid disclosure of individual company confidential data.

Synthetic mullite production showed a noticeable drop, both in tonnage and value, compared with 1974. Output in 1975, coming from five companies, was largely high-temperature sintered material. Producers were A.P. Green Refractories Co. at Philadelphia, Pa.; C-E Minerals, Inc. at Americus, Ga.; Harbison-Walker Refractories at Eufala, Ala.; and Taylor Refractories Division, NL Industries, Inc. at Greenup, Ky. Electric-furnace fused mullite was produced by the Carborundum Co. at Niagara Falls, N.Y.

---

1974 [r]	41,508	5,895
1975	24,147	3,350

[r] Revised.

CONSUMPTION AND USES

Kyanite and related materials, conforming to the established end use pattern, were consumed in 1975 mostly in the manufacture of high-alumina or mullite-class refractories and in lesser quantities as ingredients in some ceramic compositions. Imported Indian kyanite was calcined in its natural lump form, after which it was usually separated into designated particle-size ranges for use chiefly as a grog. Domestic kyanite, already ground to minus 35-mesh as required by the flotation process used in its separation and recovery, was marketed in the raw form or after heat treatment; that is, as mullite, which was sometimes further reduced in particle size before use. In the 35- to 48-mesh range, the mineral was used mostly in monolithic refractory applications such as for high-temperature mortars or cements, ramming mixes, and castable refractories, or with clays and other ingredients in refractory compositions for making kiln furniture, insulating brick, firebrick, and a wide variety of other refractory articles. More finely ground material, minus 200-mesh for example, was used in body mixes for sanitary porcelains, wall tile, precision casting molds, and miscellaneous special-purpose ceramics.

PRICES

Engineering and Mining Journal, December 1975, listed prices for kyanite, f.o.b. Georgia, ranging from $63 to $118 per short ton for bulk shipments and $9 more per ton for bagged material.

Price ranges quoted for kyanite-group materials in Ceramic Industry Magazine, January 1976, were as follows:

	Per short ton
Andalusite	$30–$60
Kyanite	63–116
Mullite, calcined	275–285
Mullite, fused	160–450

The December 1975 issue of Industrial Minerals (London) quoted kyanite-group price ranges approximately equivalent (with some uncertainty due to a floating exchange rate) to the following:

	Per short ton
Andalusite, Transvaal, c.i.f. main European port	$82
Kyanite, Indian, f.o.b	92
Sillimanite, Indian, natural bagged, f.o.b	73 nominal
Kyanite, Indian, calcined. f.o.b. Calcutta	$174–183

FOREIGN TRADE

U.S. exports of kyanite and related minerals in 1975 showed an increase compared with 1974, while imports decreased. From 1955 to 1975, U.S. imports of kyanite minerals have diminished from 7,600 tons to 65 tons. It can be supposed that the greater part of the material currently being exported consists of mullite. It should be noted, however, that some element of uncertainty is inherent in such conclusions because the Bureau of the Census export figures, on which they are based, do not clearly distinguish synthetic mullite from some other mullite-containing materials prepared by high-temperature processing of certain bauxitic and kaolinitic minerals.

WORLD REVIEW

Complete statistical information is not available on foreign production of kyanite-group minerals and materials. Although official data are not available, it was estimated that in excess of 77,000 tons of kyanite and related minerals was produced in the U.S.S.R. in 1974. Interest was being maintained in potential kyanite deposits in Austria, Botswana, Canada, Kenya, Liberia, Malawi, Norway, Scotland, the Republic of South Africa and Tanzania.[2]

Brazil.—Plans were made to build a mine-mill facility in Minas Gerais State to produce refractory-grade kyanite. The company, Mineração Interex do Brasil Ltda., is a joint venture between Adela Empreendimentos of São Paulo and Nord Resources of Albuquerque, N. Mex. The project will require an estimated $800,000 to construct a 16,500-ton-per-year kyanite plant, with the new facility scheduled to be onstream in mid-1976.[3]

France.—Denain-Anzin Minéraux reported andalusite production of slightly under 11,000 tons in 1974 from their Glomel deposit in Brittany. Recently installed facilities are producing ground material in different mesh sizes. New capacity was to be put into operation by the end of 1975, bringing output capability of Glomel to 44,000 tons per year.[4]

Germany, West.—Imports of kyanite-group minerals amounted to 21,035 tons in 1973. The principal countries of origin and the percent supplied were the Republic of South Africa 41%, India 24%, the United Kingdom 17%, and France 8%. In 1974, kyanite-group imports were 26,870 tons. The principal suppliers and the share provided were the Republic of

[3] Engineering and Mining Journal. V. 176, No. 10, October 1975, p. 159.

[4] Work cited in footnote 2.

South Africa 35%, India 23%, the United Kingdom 17%, and France 12%.[5]

India.—Indian production of kyanite is derived from three localities. The Lapsa Buru deposit contains a high quality kyanite. The Geological Survey of India has estimated kyanite reserves of 60% to 62% Al_2O_3 at 4.2 million tons. Apart from this are 74.3 million tons of 30% kyanite-quartz rock in the Singhbhum district, the potential of which has yet to be evaluated.[6]

Production of sillimanite has been in the range of 3,500 to 4,500 tons per year, and reserves, estimated at 500,000 tons, are ample. To meet a domestic demand of 16,500 tons per year, however, production would have to be raised and additional resources assessed (for example, the sillimanite-quartz rock deposits in Karnataka).[7]

At yearend 1975, Rare Earth Ltd. was constructing a $2.9 million monazite sand separation plant on a 26-square-mile area in Gopalpur in Southern Orissa. Various minerals are to be produced, including an estimated initial annual output of 60,000 tons of sillimanite.[8]

At the end of 1973, the Geological Survey of India reported finding an andalusite deposit covering 6 square miles near Nagar Untari in Bihar. Reserves were tentatively estimated at 4 million tons of ore per yard depth.[9]

South Africa, Republic of.—The Republic of South Africa, the leading producer of sillimanite among market economy countries, has deposits of sillimanite-corundum rock occurring in schists and gneisses. The sillimanite-bearing schists have an alumina content of 55% to 60%, but the extremely hard sillimanite-corundum rock can be as high as 75% Al_2O_3. Production was down during the first half of 1974 compared with 1973, but exports were being maintained at the usual level of 7,500 tons during January-June 1974.

Large deposits of andalusite exist in the Transvaal. Production in the first half of 1974 was 36,000 tons, with about 20% being exported.[10]

[1] Owing to incomplete reporting, the table has not been totaled.

[2] In addition to the countries listed, a number of other countries presumably produce kyanite and related minerals, but output data are not reported and no basis is available for estimates of output levels.

[3] In addition, sillimanite clay (also called kaolinized sillimanite) is produced, but available information is inadequate to make reliable estimates.

TECHNOLOGY

Drilling programs on ore bodies immediately adjacent to their current mining operations were conducted by both major kyanite producers (C-E Minerals, Inc. and Kyanite Mining Corp.). This resulted in the further increase of their already large proven ore reserves. What reportedly could be the world's largest kyanite deposit was purchased by Kyanite Mining Corp. The Crocan Lake deposit, near North Bay, Ontario, is said to contain at least 50 million tons of ore occurring to an explored depth of 100 feet.

In 1975, the expansion of the C-E Minerals' Graves Mountain plant increased the company's capacity to 70,000 tons per year. Construction continued on Kyanite Mining's third concentrating plant, at the East Ridge deposit, immediately east of Willis Mountain. This new plant is scheduled for completion by fall 1976, with a productive capacity of 100,000 tons per year.

[9] Work cited in footnote 2.

[10] Work cited in footnote 2.

In the Western United States, Ethyl Corp. continued its development program at Woodrat Mountain, Idaho. The company was reportedly looking for an electrolytic plant site with 400,000 kilowatts per year of guaranteed power to process the kyanite concentrates into a new product.[11]

Construction was underway in 1975 on a blast furnace, said to be the largest in the Western Hemisphere, at Bethlehem Steel Corp., Sparrow's Point, Md. Some use was made of mullite refractories in the stoves.[12]

For many practical applications of ceramic materials, it is desirable to know certain properties of these materials. In conjunction with this, a commercial mullite material was analyzed with respect to its composition, microstructure, and mechanical properties.[13]

Lead

By J. Patrick Ryan [1] and John M. Hague [1]

In 1975, world mine production of lead declined slightly from the 1974 level, but remained near the average of the last 5 years at about 3.80 million tons. Smelter production was 3.71 million tons, down about 4% from the peak output achieved in 1974. World metal consumption decreased about 10% and was moderately less than metal production; the excess production was balanced by a net buildup in producers' and other stocks. Only minimal sales were made from the U.S. Government stockpile during the year. World producers' stocks outside centrally planned economy countries increased from approximately 270,000 tons at the beginning of the year to 360,000 tons at the end of May, declined thereafter to 266,000 tons in October, and rose again to 296,000 tons at yearend. Consumer stocks declined during the year in the United States and the United Kingdom but increased in Japan. The U.S. producer price of lead remained at 24.50 cents per pound through the first quarter, virtually at parity with the London Metal Exchange (LME) price. It then dropped to 22.5 cents in May and to 19 cents in June, increased to 20 cents through November, and dropped to 19 cents in December. During the last 3 quarters, the U.S. producers price was 3 to 4 cents above the equivalent LME cash price, which was about 15.5 cents per pound at yearend.

Domestic mine production decreased 6% from the record high level of 1974 to 621,500 tons in 1975. Primary refinery output from domestic and foreign concentrates also declined about 7% to 638,250 tons. Secondary smelter output dropped to 658,500 tons, nearly 6% below the record output of 1974.

U.S. consumption of lead, reflecting the falloff in demand attributed to the general business recession, declined to 1.30 million tons, about 19% below the record high reported in 1974 and the lowest level of consumption since 1967. Most of the decline was in the transportation sector of the economy; batteries for the automotive industry and antiknock additives in gasoline, which together accounted for 70% of total lead consumption, were down 18% and 17%, respectively. Lead used in pigments, ammunition, and most other metal products was also substantially less than in 1974.

Stocks of refined and antimonial lead at primary plants increased 44,000 tons during the year to 81,300 tons at yearend. Consumers' stocks of refined soft lead and lead in antimonial lead and other alloys declined from 165,400 tons in January to 131,700 tons at yearend.

Legislation and Government Programs.—The General Services Administration (GSA) reported that commitments to purchase surplus lead from the Government stockpile fell sharply in 1975. Sales were suspended in the third quarter when stocks held by primary producers reached the cutoff level. The stockpile objective was unchanged at 65,100 tons. The uncommitted stockpile surplus at yearend was 536,519 tons, of which 71,621 tons was available for disposal under long-term contracts. Actual physical drawdown of government stocks during 1975 was about 7,000 tons, leaving a total inventory in storage of 601,670 tons on December 31.

The Environmental Protection Agency (EPA) under authority of the Federal Water Pollution Control Act, as amended, published proposed effluent limitations and guidelines for existing and new ore mining and dressing facilities to be achieved by the application of best available technology. The quantity of pollutants discharged in mine drainage from lead-bearing ores and from mills employing the flotation process will be limited to a maximum for any 1 day of 0.4 milligrams per liter and shall not exceed an average of 0.2 milligrams per liter for 30 consecutive days.

[1] Physical scientist, Division of Nonferrous Metals.

The Electric Vehicle Research, Development, and Demonstration Act of 1975 (H.R. 8800) was introduced in the 94th Congress, 1st session. The bill authorizes a Federal program to promote electric vehicle technologies and demonstrate the commercial feasibility of electric vehicles. The research, development, and demonstration program would be carried out by the Energy Research and Development Administration (ERDA). The bill was read twice and referred to the Senate Committee on Commerce. If enacted, the legislation could have a major impact on lead-acid battery manufacturers and the lead-mining industry.

The Occupational Safety and Health Administration (OSHA) revised workplace standards for lead by reducing permissible employee-exposure limits from 200 micrograms to 100 micrograms per cubic meter of air based on an 8-hour time-weighted average. Implementation of the standard would require all employers in whose workplace there is lead, inorganic lead compounds, or organic lead salts, to make an initial determination of whether employee exposure to lead exceeds an "action level" of 50 micrograms per cubic meter of air. Where levels exceed the permissible 100-microgram limit, employers must use all "feasible engineering controls" to reduce exposures.

The full U.S. Circuit Court of Appeals for Washington granted a rehearing on a petition by EPA of a three-judge panel decision in December 1974 that ruled EPA's phasedown of lead-in-gasoline regulations were invalid. The rehearing was held on May 30, 1975, but no decision had been issued at yearend.

The International Lead and Zinc Study Group (ILZSG) held its 19th session in Geneva, Switzerland, November 3–8 to review the situation and outlook for lead and zinc. ILZSG provided estimates of production and consumption of lead and zinc that reflected changes brought about by the sharp downturn in world economic activity in 1975, and forecast increases in metal output and consumption in 1976 based on improved economic conditions. A review of new mine and smelter projects disclosed plans for several new secondary lead smelter projects and small increases in lead- and zinc-mine capacity in many countries.

[1] Quotation for 1971 at New York and for 1972–75 on a nationwide, delivered basis.

DOMESTIC PRODUCTION

MINE PRODUCTION

U.S. mine output of lead in 1975 dropped 6% to 621,500 tons from the record high achieved in 1974. Monthly production reached a maximum of 58,500 tons in March, about 6,500 tons less than the maximum achieved in October 1974. Production from Missouri mines decreased 8% to 516,000 tons and accounted for 83% of the Nation's total output of lead. Production in Idaho, which provided 8% of the total, was down 1,300 tons from the 1974 level. Colorado's production increased 2,500 tons, largely reflecting a substantial gain in ore treated at the Resurrection mine. Utah's output of lead rose 21% in 1975 from the more than 70-year low recorded in 1974. Lower production at Kennecott Copper Corp.'s Burgin mine was more than offset by new production at the Ontario mine near Park City, which began operations in May 1975. The Ontario mine is a joint venture of ASARCO Inc. and The Anaconda Company, and is managed by the latter.

The Buick mine, jointly owned by AMAX Lead Co. of Missouri and Homestake Mining Co., was the Nation's leading lead producer for the fifth consecutive year, with a record output of ore. However, lower lead and zinc grades kept lead-concentrate production at approximately the same level as in 1974, and zinc concentrate production was 9,400 tons less than in 1974. Ore milled in 1975 totaled 1.63 million tons averaging 11.7% lead and 3.6% zinc, from which 251,500 tons of lead concentrate and 45,800 tons of zinc concentrate were produced. Total ore reserves increased 1.6 million tons during the year to nearly 28.4 million tons at yearend. Average grade of the reserves was 7.1% lead and 2.0% zinc compared with an average of 8.1% lead and 2.2% zinc at yearend 1974.[2]

The seven leading mines, all in Missouri, contributed 79% of the total U.S. mine production of lead. The 12 leading mines produced 91%, and the 25 leading mines accounted for 99% of the total. About 4,600 persons were employed at the Nation's lead, lead-silver, and lead-zinc mines and mills in 1975. Output of lead and zinc from these mines was approximately 173 tons per man-year. Average grade of lead ore mined was 6.17% lead and 0.89% zinc, compared with 6.24% lead and 1.01% zinc in 1974.

In Missouri, St. Joe Minerals Corp., the Nation's largest lead-mining company, cut back operations at its four southeast Missouri mine-mill units during part of the year. The 1975 production of lead in concentrates was reported at 201,434 tons, 46,060 tons less than in 1974. St. Joe's four mine units—Fletcher, Viburnum, Indian Creek, and Brushy Creek—accounted for approximately one-third of U.S. mine production in 1975. The corporation reported that its productivity index, tons produced per man-shift worked underground, increased as a result of extensive automation from 30.8 at the older facilities to 56.8 at the newest, Brushy Creek[3]

In Idaho, Hecla Mining Co. reported that its Lucky Friday mine produced 173,245 tons of ore assaying 10.71% lead, 1.29% zinc, and 14.96 ounces of silver per ton in 1975, compared with 165,700 tons assaying 9.93% lead, 1.18% zinc, and 13.53 ounces of silver per ton in 1974. About 18,300 tons of lead was recovered in the concentrates produced. Ore reserves at Lucky Friday at yearend were 505,000 tons, compared with 539,000 tons reported a year earlier. Hecla also reported that ore production at the Star-Morning mine, jointly owned by Hecla (30%) and The Bunker Hill Co. (70%), increased slightly to 282,160 tons. Hecla's share of the 1975 production was 84,648 tons assaying 5.00% lead, 5.64% zinc, and 2.49 ounces of silver per ton. The concentrates produced yielded about 3,900 tons of lead. Hecla's 30% share of the computed ore reserves increased 18,000 tons to 394,000 tons at yearend.[4]

The Bunker Hill Co. reported that production from company owned and controlled mines aggregated 33,000 tons of lead, 2,000 tons more than in 1974. The company also reported that proven and probable ore reserves at yearend in the Bunker Hill mine totaled 3.08 million tons averaging 2.3% lead, 3.5% zinc, and 1.3 ounces of silver per ton. In addition, the company's 70% interest in the proven and probable reserves of the Star mine totaled 699,000 tons averaging 7.1% lead, 7.8% zinc, and 4.1 ounces of silver per ton.[5]

[4] Hecla Mining Co. 1975 Annual Report. Pp. 6–7.

In Colorado during 1975, Idarado Mining Co. treated 406,000 tons of lead-zinc-copper ore averaging 2.28% lead, 3.24% zinc, and 0.63% copper, compared with 396,600 tons averaging 2.46% lead, 3.33% zinc, and 0.55% copper treated in 1974. Ore reserves at yearend 1975 decreased 6% to 3.66 million tons averaging 3.05% lead, 4.42% zinc, and 0.67% copper. The company reported that major negative factors in 1975 were higher mine operating costs and sharply increased smelter treatment charges. At the Leadville Unit mine also known as the Resurrection mine, a joint venture of ASARCO, Inc. and Newmont Mining Corp., 203,000 tons of lead-zinc-silver ore was treated, about 40,000 tons more than in 1974. The average grade of ore milled in 1975 was 4.23% lead, 8.68% zinc, and 2.2 ounces silver per ton, compared with 4.49% lead, 9.60% zinc, and 2.5 ounces of silver per ton in 1974. Ore reserves at the Resurrection mine at yearend 1975 were estimated at 2.27 million tons averaging 5.1% lead, 9.9% zinc, and 2.7 ounces of silver per ton. Although total ore reserves declined 14% in 1975, the average grade was slightly higher than in 1974.[6]

SMELTER AND REFINERY PRODUCTION

Output of primary refined lead and lead in antimonial lead from the Nation's five primary refineries in 1975 totaled 638,247 tons, about 7% less than the 46-year production record achieved in 1974. About 83% of the total output was recovered from domestic ores, compared with 85% in 1974. Antimonial lead production at primary refineries dropped to 6,029 tons, less than one-half of 1974 production. The average antimony content of the alloy increased from 8.8% to 9.4%.

At the Herculaneum, Mo., smelter of St. Joe Minerals Corp., production of lead and lead alloys in 1975 totaled 185,890 tons, 19% less than in 1974. The falloff in metal production was attributed largely to a reduction in smelter operations to 60% of capacity during part of the year.[7]

ASARCO reported that its Omaha, Nebr., and Glover, Mo., refineries produced 200,100 tons of lead, about 8% less than in 1974. The company also reported that major environmental improvements were being designed at its El Paso, Tex., smelter to meet State air-quality standards. These include a totally enclosed ore-handling system, a new lead sinter plant, and an acid plant to treat sinter plant gases. At East Helena, Mont., a 400-ton-per-day acid plant was being constructed to meet clean air requirements. The East Helena smelter modifications and new facilities were scheduled for completion in 1977, and those at El Paso were to be completed in 1978. Base bullion produced at the East Helena and El Paso custom smelters were treated at the Omaha refinery. Most of the concentrate treated at the Glover smelter-refinery was produced at the Kennecott Copper Corp. Ozark mine at Sweetwater, Mo. The East Helena smelter processed ores and concentrates from about 125 domestic mines in 9 States and from mines in Australia, Canada, Colombia, and Peru. The El Paso smelter processed ores and concentrates from approximately 40 domestic mines in 8 States and from mines in Australia, Canada, Colombia, Honduras, Nicaragua, and Peru. The company reported that a new ventilating system was being installed to meet OSHA standards and that it had completed a closed-circuit water system to eliminate discharge of liquid effluent from the plant property.[8]

The AMAX-Homestake smelter-refinery at Boss, Mo., produced 136,000 tons of refined lead from the treatment of 197,000 tons of concentrates in 1975, 1,800 tons more lead than in 1974. Approximately one-half of the metal produced was derived from concentrates treated on toll. The company reported that gaseous and liquid effluents have been effectively controlled through close monitoring of the air and streams of the surrounding area.[9]

The Bunker Hill smelter-refinery of Gulf Resource and Chemical Corp. produced 123,000 tons of lead, about the same as in 1974. The company reported that productive operations approached capacity during the first 7 months of 1975 despite periodic curtailments to meet environmental regulations governing the emission of sulfur oxides. More stringent regulations effective August 1, combined with unusually adverse weather conditions, necessitated more frequent and longer smelter interruptions and some loss of production in the fourth quarter. The Bunker Hill smelter processed concentrates from mines in seven States, and Canada, Greenland, and Peru.

[9] Page 8 of work cited in footnote 2.

Secondary smelter production from recycled materials in 1975 dropped nearly 6% below the record output of 1974 to 658,500 tons, about 51% of the total smelter and refinery production. Approximately 115 secondary plants were engaged in recovering lead and lead alloys from recycled scrap materials during the year. Five plants closed during the year. Secondary metal output represented about 51% of total lead consumption in 1975. Approximately 41% of the total secondary lead production was recovered in the form of lead metal, and the remainder, as antimonial lead and other lead alloys.

RAW MATERIAL SOURCES

Primary smelters and refineries processed ores and concentrates from domestic mines yielding 531,900 tons of refined lead and antimonial lead, about 83% of the total refinery production. Refined and antimonial lead recovered from imported concentrates smelted during the year totaled 106,400 tons, 9,440 tons more than in 1974. Lead recovered from lead scrap processed at primary plants increased nearly 1,800 tons to about 3,300 tons contained in antimonial lead.

Scrap materials consumed in 1975 totaled 909,300 tons, about 19,900 tons less than in 1974. New scrap in the form of purchased drosses and residues from a variety of sources aggregated 136,100 tons, about 15% of the total scrap processed, compared with 129,400 tons, about 14% of the total input, in 1974. The remainder, old scrap, was largely battery plates, with smaller quantities of cable lead, soft and hard lead, type metal, solder, and babbitt. A small amount of reclaimed scrap totaling about 5,400 tons in 1975 was imported for processing in domestic plants.

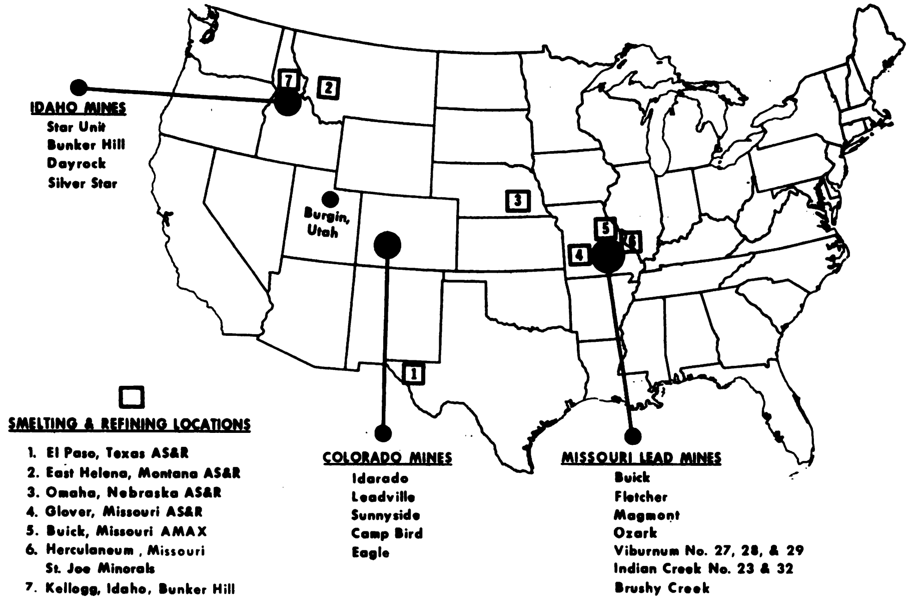

Figure 2.—Lead mines and smelters in the United States.

CONSUMPTION AND USES

Domestic consumption of lead in 1975 dropped to 1.30 million tons, 19% below the record high of 1974 and the lowest level of consumption since 1967. On a monthly basis, consumption ranged from a low of 88,600 tons in July to a high of nearly 133,700 tons in October. The use of lead declined in all major product categories. In metal products, battery requirements dropped 18%, ammunition was down 14%, and solders declined 13%. Lead used in pigments, principally red lead and litharge, was down 32%, and lead used in gasoline antiknock compounds decreased 17%. Miscellaneous and other unclassified uses of lead combined were 12% less than in 1974. According to type of material consumed, soft refined lead represented 66% of the total consumption; antimonial lead accounted for 29%; and lead in other alloys, mainly solders and bearing metals, accounted for 4%. Lead in copper-base scrap accounted for 1% of the total consumption.

The 18% falloff in lead requirements for battery grids and oxides was attributed essentially to the reduction in output of motor vehicles using batteries for starting, lighting, and ignition (SLI). Approximately 47.2 million batteries of this type were produced in 1975, 8.5 million less than in 1974. Of the total battery production, about 40.7 million were replacement and 6.5 million were original equipment. The 17% drop in the quantity of lead used in antiknock compounds in 1975 reflected a reduction in the average lead content per gallon of gasoline from about 1.9 grams per gallon in 1974 to approximately 1.7 grams per gallon in 1975. This was a result of increased production of unleaded gasoline, in conjunction with a decrease in the output of premium gasoline. Lead used in battery manufacture accounted for about 54% of total lead consumption. Lead requirements for antiknock compounds represented 16% of the total; pigments accounted for 6%; ammunition, 6%; miscellaneous and other unclassified uses, 3%; and other metal products, the remaining 15%.

The domestic supply of lead metal from all sources—primary and secondary production, imports for consumption, industry stock changes, and stockpile releases—totaled about 74,100 tons (5%) more than reported consumption and exports. The apparent excess supply in 1975 was attributed largely to unreported consumption, incomplete export data, and stock buildup, especially by small producers and dealers that do not report to the Bureau of Mines.

LEAD PIGMENTS

Pig lead used in the production of lead oxides and pigments totaled nearly 495,700 tons, about 11% less than in 1974. The quantity of lead used in making black oxide decreased 11% and accounted for 71% of the total lead in pigments. Litharge production was down 13% and accounted for 25% of the total pigment and oxide production in 1975. Most of the litharge and black oxide produced went to battery manufacturers. Litharge shipments for use in the ceramics industry dropped 27% and accounted for 28% of the total litharge shipments.

Prices.—The published price of basic carbonate white lead in carload lots, freight allowed, which had remained unchanged at 23.9 cents per pound through 1973 and 1974, was advanced to 32.5 cents per pound in January. It then remained unchanged through December 1975. The quoted price of red lead (Pb_3O_4) 95%, in carload lots at works, was unchanged at 29.25 cents per pound through May, then was reduced early in June to 27.75 to 28.0 cents, and remained unchanged thereafter to yearend. The price quotation on lead silicate ($PbSiO_2$) remained unchanged at 23 cents through mid-August, then was advanced to 25.05 to 26.05 cents per pound, remaining unchanged through December. Commercial-grade litharge in carload lots at works was quoted at 28.50 to 29.50 cents per pound through the first 5 months of 1975. The price was reduced in the first week in June to 27 to 27.75 cents, and reduced again in August to 24.50 cents, remaining unchanged thereafter to yearend.

The value of shipments of white lead, red lead, and litharge amounted to $59.4 million, an average of $428 per ton, compared with $89.2 million and $494 per ton in 1974.

Foreign Trade.—Exports of pigment-grade and other lead oxides totaled nearly 2,300 tons valued at $1.39 million. Shipments went to 33 countries. Imports for consumption of lead pigments and compounds increased 7% in quantity, but the value decreased 25% to $7.5 million. Litharge, which comprised 78% of the total quantity imported, increased 39%; imports of chrome yellow, comprising 16% of the total, were 43% less than in 1974. Nearly all of the imports of litharge came from Mexico; most of the chrome yellow came from Japan.

STOCKS

Inventories of refined and antimonial lead at primary smelters and refineries increased steadily during the first 7 months from about 37,300 tons at the beginning of the year to nearly 110,000 tons in July, then trended downward to 81,300 tons at yearend. Stocks of lead in base bullion were about 1,300 tons more than that of 1974, but lead in ore and matte stocks dropped 9,800 tons to 68,500 tons at yearend.

Stocks of lead in all forms at consumer and secondary smelter plants trended downward during the year from a high of 166,600 tons in January to a low of 114,100 tons in September, but rose to 133,300 tons at yearend. Refined soft lead constituted 64% of the total and lead in antimonial lead, 31%.

Stocks of refined lead, lead in antimonial lead, and lead in alloys at producers' and consumers' plants totaled 213,000 tons, representing about 2 months of domestic consumption. Stocks of new and old scrap at secondary smelters decreased about 9,000 tons to about 95,300 tons at yearend.

Lead stocks in LME warehouses increased steadily during the year from 21,760 tons early in January to 94,000 tons at yearend.

PRICES

The U.S. producer price for common and corroding-grade lead on a nationwide basis as reported by Metals Week remained unchanged at 24.50 cents per pound until May 1, when ASARCO reduced its price to 22.75 cents. ASARCO was followed by other producers, both primary and secondary, later in the month. ASARCO and other producers again reduced the price of lead from 22.75 cents to 19.00 cents in the first week in June, and this price remained unchanged until mid-August when the price was advanced 1 cent to 20 cents per pound. In mid-December, the producers' price was reduced to 19 cents per pound and remained at that value to yearend. The weighted average price for the year was 21.53 cents per pound, compared with 22.53 cents in 1974.

The LME cash bid price in terms of U.S. currency fluctuated in a narrow range near the U.S. producer price during the first quarter of the year, trending downward in April to an average of 21.73 cents. The price continued to decline from 20.93 cents on May 2 to 15.75 cents per pound on May 30, averaging 19.1 cents for the month. The average LME price for June was 15.99 cents. In July, the LME cash bid price ranged from 16.3 cents at the beginning of the month through a low of 15.8 cents at midmonth to 17.1 cents near monthend. In August, the price ranged between 16.8 cents and 17.9 cents, averaging 17.4 cents for the month. The LME price trended downward in the last 4 months to a low average of 15.10 cents in December. The equivalent average LME cash price for the year was 18.73 cents per pound (based on a monthly average Sterling Exchange rate of 222.15 cents), compared with an average 1974 price of 26.83 cents (with Sterling Exchange averaging 233.93 cents).

FOREIGN TRADE

Exports of lead metal, lead alloys, and lead in scrap materials totaled 71,200 tons, about 41% less than in 1974. Metal and alloy exports totaled nearly 21,300 tons, about one-third the quantity exported in 1974. Scrap exported (50,000 tons) was about 10,000 tons less than in 1974. On a monthly basis, metal exports ranged from a high of about 6,900 tons in April to a low of 150 tons in December, averaging 1,770 tons per month. Scrap exports ranged between a high of nearly 7,600 tons in April and a low of about 2,000 tons in August, and averaged 4,160 tons per month. More than 70% of the total wrought and unwrought metal exported went to Belgium-Luxembourg and the Netherlands. About one-third of the scrap shipments went to Canada, and the remainder, to about 21 other countries. In addition, 150,800 tons of lead and zinc concentrates valued at $31.5 million was exported. Although no breakdown by metal type or metal content is available, about 80% of the total shipments went to nine European countries and the remainder went to seven other countries.

General imports of lead materials into the United States in 1975 were nearly 10% less than in 1974. Receipts of lead in concentrates and other unrefined materials were down 7% to 87,560 tons, and metal receipts dropped 15% from the 1974 level of imports to about 100,500 tons, the smallest quantity of metal imported since 1939. The falloff in lead imports in 1975 was attributed essentially to decreased industrial demand and the high level of domestic stocks. The decline in imports of concentrates from Australia and Peru, 18% and 40%, respectively, was only partially offset by an 81% gain in receipts from Canada, a small increase in shipments from Honduras, and initial shipments from Greenland. Metal receipts from Canada and Peru, continuing a declining trend since 1972, were down 23% and 50%, respectively, in 1975. Shipments from Australia dropped to zero, but metal imports from Mexico were slightly higher than in 1974.

Canada was the leading supplier of crude lead materials, accounting for about one-third of total imports; shipments from Honduras, Australia, and Peru accounted for most of the remainder. Canada, Mexico, and Peru supplied 80% of the total metal imported.

Basic tariff rates remained unchanged in 1975 at 0.75 cent per pound on ore and concentrates and 1.0625 cents per pound on bullion, metal, and dross.

WORLD REVIEW

Mine production of lead in 1975 by market economy countries totaled 2.78 million tons, about 3% more than in 1974. Smelter production of lead in market economy countries, limited to primary metal where such information was available, totaled 2.65 million tons, slightly more than in 1974. Yugoslavia is included with market economy countries for the first time, accounting for the apparent gain in production. The mine production of centrally planned economy countries, except Yugoslavia, was estimated to be 1.01 million tons, and smelter production was about 1.06 million tons. It is likely that the imbalance results from the fact that some of the assigned smelter production includes metal from secondary sources.

World mine production declined 1% from 3.83 million tons in 1974 to 3.79 million tons in 1975, and smelter production dropped 4% from 3.86 million tons to 3.71 million tons.

The United States, the leading country in producing lead from mine sources, accounted for 16% of the world total. Other countries producing over 100,000 tons of lead in mined ore, in descending order of production, were the U.S.S.R., Australia, Canada, Peru, Mexico, Yugoslavia, Bulgaria, North Korea, and the People's Republic of China.

The United States was also the leading producer of refined lead. The U.S.S.R. probably ranked second, followed by Australia, Japan, Mexico, Canada, Yugoslavia, France, Belgium, Bulgaria, the People's Republic of China, North Korea, and West Germany; each of these 13 countries produced over 100,000 tons of lead and, collectively, accounted for 81% of world production. The smelter outputs assigned to Yugoslavia, Belgium, and Bulgaria may include recovery from secondary materials.

ILZSG reported preliminary data on consumption of refined lead in market economy countries as being at least 3.34 million tons in 1975, about 18% less than the final figure of 4.07 million tons reported for 1974. The United States was the leading consuming country, accounting for 34% of world market economy consumption. Consumption figures include metal from secondary sources. The group's reports of world lead-metal production indicate a surplus of production over consumption of approximately 87,000 tons in 1975. The surplus was probably added to producers' stocks.

Australia.—Mine production of lead increased 8% over that of 1974 to 448,700 tons in 1975. Australia was the world's third-ranking source of mined lead. Broken

Hill mines, operated close to capacity by Zinc Corporation and New Broken Hill Consolidated, produced 178,000 tons (lead content). Mount Isa Mines Ltd. increased lead production by a small margin, producing lead concentrate from silver-lead-zinc ores and smelting the concentrate to bullion at the mine site.

The combined production of refined lead and lead bullion in Australia was 342,600 tons, 8% less than 1974 output. Mount Isa Mines produced 145,000 tons of lead bullion for further refining in the United Kingdom. Broken Hill Associated Smelter Pty. Ltd. at Port Pirie produced 184,000 tons as refined lead, and Sulphide Corp. Pty. Ltd. produced 23,000 tons of lead bullion for refining elsewhere.

Consumption of primary lead in Australia declined 2% in 1975 to a total of 53,000 tons. Batteries accounted for 48% of the total; cable covering, 15%; pigments and chemicals, 10%; sheet and pipe, 9%; and other lead products, 18%. Secondary lead, used mainly by the battery industry, probably added 35,000 tons or more to primary usage.

One of the world's large undeveloped resources of lead is in the McArthur River area in the Northern Territories. During 1975, M.I.M. Holdings Ltd., parent of Mount Isa Mines Ltd., initiated a $7 million program of metallurgical testing for a feasibility study. The complex nature of the lead and zinc sulfides in the deposits posed a difficult beneficiation problem. The deposit was estimated to contain 209 million tons averaging 9.5% zinc, 4.1% lead, and 40 grams of silver per ton.

M.I.M. continued development of the Hilton mine 11 miles northeast of Mount Isa. Work included bulk ore sampling for pilot plant tests.

Bolivia.—Corporación Minera de Bolivia (COMIBOL) provided a large part of Bolivia's foreign exchange earnings through metal exports. The recent increases in the development of Bolivian mines created a market for sales of U.S. mining machinery and equipment. Although lead is not the major mineral product, COMIBOL exported 15,700 tons of lead in 1975 and produced 13,040 tons from six of the mines that it operated. Other minerals beside lead showed an excess of exports over production in 1975. The "medium miners" and "small miners" added to the export tonnage to make total exports of 19,500 tons of lead, mainly as concentrates.

Empresa Nacional de Fundiciones (ENAF) and COMIBOL formed a joint company in 1975 to construct a $35 million lead-silver smelter with a capacity of 27,500 tons of lead and 4.8 million troy ounces of silver per year. Construction was to begin in 1978. Reserves of lead ore estimated by COMIBOL at the end of 1975 were 2,300,000 tons containing 57.300 tons of lead.

Burma.—The Burmese Government planned to modernize the Bawdwin lead-zinc mine with West German financial assistance. Burmese production was 11,600 tons of refined lead, mainly from the Bawdwin mine. In fiscal year 1974–75, the Bawdwin mine produced over 166,000 tons of ore from which lead, antimonial lead, zinc, copper, nickel, and silver were recovered.

Canada.—Mine production of lead in ores and concentrates was restrained by world economic conditions in 1975 but recovered in part from the low level of 1974 to about 395,000 tons, a 12% increase. Production of primary refined lead increased 36% to 190,000 tons in 1975.

The 1974 ruling concerning dumping of lead imports into the United States was directed against Canada and Australia. In 1975, Canadian producers filed a petition seeking revocation of the findings and the U.S. International Trade Commission scheduled a hearing in July 1975. Hearings were postponed until January 1976 and, subsequently, the dumping tariffs were removed. Despite the repressive influence of the dumping hearings, Canada remained the largest source of U.S. imports of lead, providing 31% of the total of concentrates and metal imported. Of the total U.S. imports from Canada in 1975, 29,000 tons were in concentrates and 31,000 tons as metal, compared with 1974 imports of 16,000 tons in concentrates and 40,000 tons as metal.

Mine output of lead was from zinc-lead mines in eight territories and Provinces: Yukon Territory, 37%; British Columbia, 20%; Northwest Territories, 20%; New Brunswick, 17%; Newfoundland, 3%; Ontario, 2%; and Quebec and Manitoba each, less than 1%. The largest producer, Cyprus Anvil Mining Corp. at Faro, Yukon Territory, milled 3,225,000 tons of ore containing 129,000 tons of lead. The second- and third-ranking sources were Pine Point Mines, Ltd., in the Northwest Territories, producing about 75,000 tons, and the Sullivan mine at Trail, British Columbia, producing in the range of 70,000 to 76,000 tons of lead. The Brunswick Mining and Smelting Co., a subsidiary of Noranda Mines Ltd. in New Brunswick produced 59,700 tons of lead, principally from the No. 6 mine. The Buchans mine in Newfoundland, operated by ASARCO, produced concentrates containing 11,900 tons of lead.

Canadian lead-metal production came from the Cominco Ltd. smelter and refinery at Trail, British Columbia, and the Brunswick smelter at Belledune, New Brunswick. The Cominco plant produced 138,000 tons and the Brunswick smelter produced 50,900 tons of lead in 1975, but both operated far below their rated annual capacities of 225,000 and 70,000 tons, respectively.

The excess of lead concentrate production over that treated at the two smelters was exported to Japan, 40%; West Germany, 16%; the United States, 14%; the United Kingdom, 8%; Belgium, 7%; France, 1%; and the balance (14%) to other countries.

Ireland.—The Tynagh mine in County Galway, owned by Irish Base Metals Ltd. (a subsidiary of Northgate Exploration Ltd.), operated throughout 1975, producing 648,000 tons of ore with a grade of 3.94% lead, 4.27% zinc, 0.19% copper, and 1.64 ounces of silver per ton. The direct operating costs reported for 1975 were $13.78 per ton of ore mined.

The mine at Silvermines in County Tipperary, operated by Mogul of Ireland Ltd., milled 914,000 tons of ore containing 2.36% lead and 6.58% zinc. Total operating costs were approximately $12 million, or $13.17 per ton of ore.

Two companies continued development of the zinc-lead mines at Navan. Tara Exploration and Development Co. Ltd., the discoverer of the deposit, reported that its expected production would be 2.5 million tons per year of ore, starting in early 1977. Ore stockpiled from development work prior to June 1975 was 105,000 tons, with an estimated grade of 11.4% zinc and 2.4% lead. During 1975, Tara reached agreement with the Irish Government concerning terms of a lease giving 25% equity to the State and a royalty equal to 4.5% of profits. The other company, Bula Ltd., started to develop the upper end of the Navan ore deposit and also reached an agreement with the Irish Government granting the State a 49% interest. Bula planned to mine at a rate of 1.2 million tons per year by open pit and underground methods. Both companies agreed to send a portion of their concentrates to an Irish zinc refinery if and when such a facility is constructed. Until then, concentrates would presumably be shipped to European smelters.

Japan.—Japanese lead smelters operated at 70% of capacity during the early months of 1975 but were operating at 90% of capacity by March 31, 1976, the end of the fiscal year. Domestic mine production of lead ores contributed 55,700 tons of lead content to Japanese smelter production. Sales in fiscal 1975 were 228,000 tons of lead. Sales were divided between the major producing companies as follows: Nippon Mining Co. Ltd. 12%, Mitsubishi Metal Corp. 22%, Mitsui Mining and Smelting Co. Ltd. 17%, Sumitomo Metal Mining Co. Ltd. 11%, Dowa Mining Co. Ltd. 8%, and Toho Zinc Co. Ltd. 30%. Construction of additions to its lead smelter by Dowa at Kosaka was deferred beyond 1975. Lead exports in 1975 were 43,500 tons and imports were 15,307 tons.

Mexico.—Lead production in 1975 was adversely affected by decreased world demand and lower prices, with an 18% decrease from 240,000 tons in 1974 to 198,000 tons in 1975. Exports as bars or unrefined lead were 111,000 tons.

The Peñoles group continued construction of a smelter and refinery complex for lead and silver at Torreon, Coahuila, designed to achieve a capacity of 209,000 tons and representing an investment of $36 million. Industrial Minera Mexico, S.A., had expansion programs underway at several of its mining units designed to increase its capacity to process lead, zinc, and copper ores. Placer Development of Canada (34%), a Mexican financial group—Bancomer (33%)—and Comisión de Fomento Minero (33%) participated in Explomin, S.A. de C.V., to explore and develop the Real de Angeles silver-zinc-lead property in Zacatecas.

Late in 1975, proposed reforms to the Mining Law of 1961 were approved by the Congress, giving the Government greater control over and more participation in mining activity. The changes provided for a reduction in private sector participation, the establishment of quotas per mining unit, and restrictions on Mexicanized privately owned companies. The Government hoped that the reforms would promote greater activity by small miners and an increase in exploration to be financed by Government agencies.

Spain.—Lead-metal production in Spain was expected to grow from 81,000 tons in 1975 to as much as 140,000 tons in the next 5 years. Mine production of lead in 1975 was 64,000 tons from a complex of 77 mines and 30 treatment plants. The construction of the Rubiales zinc-lead mine and concentrator continued in 1975 and was expected to add 16,500 tons of lead concentrate to Spanish production when completed in 1977. Spain consumed 127,500 tons of lead in 1975; the apparent deficit in lead was made up by imports of concentrates and metal.

U.S.S.R.—Trade data published by ILZSG disclosed that the U.S.S.R. imported 65,500 tons of lead metal from Japan, North Korea, Peru, the United Kingdom, West Germany and Yugoslavia, and exported 11,800 tons to Finland and the Netherlands. Another source estimated that total lead-metal exports were 109,000 tons and imports were 62,500 tons. The World Bureau of Metal Statistics estimated mine production of lead in the U.S.S.R. in 1975 as 556,000 tons and consumption as 602,000 tons. Secondary lead production was estimated to be 105,000 tons.

Yugoslavia.—The program of expanding lead and zinc production continued in 1975; $15 million was budgeted for the lead share, with the aim of achieving a production of almost 200,000 tons of lead by 1980. Smelter production in 1975 was estimated at 139,000 tons of primary refined lead. Lead and zinc ores were produced from 18 mines and treated at 14 flotation plants, with concentrates going to 2 lead smelters, 1 Imperial lead-zinc smelter, and 1 lead refinery. Trepca was the major producer, with a mine at Stari Trg and a smelter and refinery at Zvecan, all in Serbia.

At the Trepca smelter, work continued on improving the sulfuric acid plant. The plant had not been in continuous operation after its construction in 1967 because of problems resulting from the low concentration of SO_2 in smelter gases. During 1975, workers were affected by gas exposure and lead poisoning, and the proposed continuous operation of the sulfuric acid plant in 1976 was intended to improve working conditions.

TECHNOLOGY

Bureau of Mines metallurgists developed a method for recovering lead from lead battery scrap that eliminates virtually all of the SO_2 normally emitted when a reverberatory or blast furnace is used. The method employs a hydrometallurgical step to convert the $PbSO_4$ to PbO and $CaSO_4$ by mixing the battery scrap with a slurry of $Ca(OH)_2$. The dried product is mixed with a KCl-NaCl flux and carbon and reduced at 650° C. The process produces lead reductions and recoveries as high as 97.0% and 94.9%, respectively. The KCl-NaCl flux is recovered.[10]

Researchers at the Bureau of Mines Reno Metallurgy Research Center investigated an alternative hydrometallurgy procedure for reducing lead sulfide concentrates that does not generate gaseous sulfur oxides and diminishes the potential for the emission of lead into the atmosphere. The procedure involves leaching galena flotation concentrate with ferric chloride ($FeCl_3$) solution to obtain lead chloride ($PbCl_2$) and elemental sulfur. High-purity $PbCl_2$ crystallizes from the leach filtrate on cooling and is electrolyzed in a low-temperature fused-salt cell to obtain corroding-grade metal. Spent leach solution ($FeCl_3$) is regenerated for further use. Other associated metals such as silver, copper, and zinc are recovered by additional steps. The process is suitable for small-scale operation, is not capital intensive, requires little labor, and can extract over 99% of the lead in concentrate in minutes.[11]

A closed lead-acid battery-reclamation furnace originally developed by Varta Batterie AG (West Germany) will be installed by Britannia Lead Co. in the United Kingdom. The furnace is designed to provide a closed operating system and achieves high temperatures using oxygen in the blast area combined with a series of afterburner chambers to complete the combustion process by insuring that all hydrocarbon particles are burned. In addition to environmental advantages, the furnace, by processing whole batteries and obviating hand operation, minimizes safety and health hazards to workers.[12]

E. I. duPont de Nemours & Co. announced the discovery of a new type of catalyst that showed promise of operating on leaded fuel while meeting the most stringent automobile emission standards. These new catalysts are based on the introduction of noble metals into a synthetic perovskite structure, where they are locked into place by other elements of the structure. These other elements reportedly provide the noble metal protection against the harmful materials typically found in exhaust gases and provide the catalysts with thermal stability.

DuPont, as a major producer of tetraethyl lead additives for gasoline, developed data showing that using leaded gasoline with the new catalyst would result in a net fuel savings over the use of unleaded fuel. According to the DuPont study, the addition of 2 grams of lead per gallon of gasoline would increase the octane rating from 87.5 to 95. Using leaded gasoline of a 95-octane rating could result in a net crude oil savings of about 6% compared with 91-octane unleaded fuel.[13]

Ethyl Corp. continued testing its lead-compatible emissions control system, called the Turbulent Flow System (TFS), and reported that automotive emissions have been reduced below levels required by the 1975–76 U.S. 49-State standards using leaded gasoline. TFS uses a turbulent-flow intake manifold, which improves the fuel and air mixture and distributes it more evenly to the cylinders. The process permits the engine to operate efficiently without misfire using lean mixtures.[14]

The International Lead Zinc Research Organization (ILZRO) reported that much of its research activity was directed toward the lead-acid battery, the lead industry's largest single market on a world basis. Significant progress also was reported in areas of environmental health, ceramics, architecture, and metallurgy, where intensive research on lead was conducted.

A study on charging methods for lead-acid batteries disclosed that gas-controlled systems are potentially more efficient than conventional charging systems. In addition, they can result in prolonged life because they avoid elevated temperatures associated with overcharging and excessive gassing, which loosen active materials from the plate structure during overcharge.

Several improvements achieved in the performance of prototype battery-powered electric vehicles, designed and built as part of an ILZRO project, were turned over to defense agencies for further testing. Cooperative research with ERDA and the Electric Power Research Institute (EPRI) was planned to establish the viability of existing lead-acid battery technology in load-leveling applications. A cell and battery system was being designed for this application.

Design criteria for ceramic glazes were developed that minimize lead release from dinnerware. Safe lead glazes can be made by keeping the molar ratio of modifying ions (alkalies or alkaline earths) to silica below 0.7. Another project showed that production of ceramic tiles from lead slags was commercially viable and that the resulting products could be made in various colors at a savings of about 40% of the cost of regular tiles.[15]

			In antimonial lead[1]	371,503	315,120
Old scrap:			In other lead alloys	72,597	58,485
Battery-lead plates	418,400	417,489	In copper-base alloys	16,361	13,523
All other lead-base	169,184	136,280	In tin-base alloys	21	31
Copper-base	13,359	10,471			
Tin-base	2	2	Total	460,482	387,159
Total	600,945	564,242	Grand total	698,698	658,456
Grand total	698,698	658,456			

[1] Includes 1,549 tons of lead recovered in antimonial lead from secondary sources at primary plants in 1974 and 3,337 in 1975.

Table 12.—Lead consumption in the United States, by product

(Short tons)

Product	1974	1975	Product	1974	1975
Metal products:			Pigments—Continued:		
Ammunition	87,090	75,081	Pigment colors	17,336	10,618
Bearing metals	14,609	12,184	Other[1]	718	499
Brass and bronze	22,240	13,404			
Cable covering	43,426	22,099	Total	116,213	79,072
Calking lead	19,739	14,296			
Castings metals	7,507	7,711	Chemicals:		
Collapsible tubes	2,488	2,216			
Foil	4,404	3,205	Gasoline antiknock additives	250,502	208,605
Pipes, traps, bends	16,455	14,233	Miscellaneous chemicals	708	181
Sheet lead	21,294	24,859			
Solder	66,280	57,344	Total	251,210	208,786
Storage batteries:			Miscellaneous uses:		
Battery grids, posts, etc	391,479	326,714	Annealing	4,097	2,629
Battery oxides	460,402	372,700	Galvanizing	1,664	1,228
Terne metal	2,300	1,511	Lead plating	498	376
Type metal	20,516	16,211	Weights and ballast	21,418	20,018
Total	1,180,229	963,768	Total	27,677	24,251
			Other, unclassified uses	24,098	21,221
Pigments:					
White lead	1,996	2,498	Grand total[2]	1,599,427	1,297,098
Red lead and litharge	96,163	65,457			

[1] Includes lead content of leaded zinc oxide and other pigments.

[2] Includes lead which went directly from scrap to fabricated products.

Table 13.—Lead consumption in the United States, by month

(Short tons)

Month	1974	1975	Month	1974	1975
January	140,971	105,091	August	143,953	115,510
February	129,404	98,866	September	143,712	122,985
March	130,884	99,216	October	156,780	133,696

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Uganda and Egypt may produce lead, but available information is inadequate to make reliable estimates of output levels.

[2] Recoverable metal content of lead in concentrates for export plus lead content of domestic products (refined lead, antimonial lead, mixed bars, and other unspecified items).

[3] Recoverable metal.

[4] Recoverable metal; content of lead in concentrates for export plus lead content of domestic smelter products (refined lead, antimonial lead, and bismuth-lead bars).

[5] May include small quantities of zinc.

[6] Data compiled from operating company reports of Tsumeb Corp. Ltd., South West Africa Co. Ltd., and South African Iron and Steel Industrial Corp. Ltd. (ISCOR) for Imcor Zinc (Pty.) Ltd's Rosh Pinah mine. Data from Tsumeb Corp. Ltd. are for calendar years; data from other companies are for fiscal years ending June 30 of the year stated.

[7] Figure comprises reported production of South West Africa Co. Ltd. and Rosh Pinah mine plus an estimate for Tsumeb Corp. Ltd.

[8] Content of concentrates.

[9] Contained in lead-copper concentrate.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Primary except as noted, or where source does not differentiate.

[2] Includes recovery from secondary materials.

[3] Refined from domestic and foreign ores; excludes lead refined from imported base bullion.

[4] Includes primary lead content of antimonial lead.

[5] Lead bullion from imported ores and concentrates.

[6] Revised to none.

Lime

Avery H. Reed [1]

Lime output in 1975, including that for Puerto Rico, declined 11% to 19.2 million tons. Total value established a new annual record, increasing 10% to $526 million.

Output of all types of lime decreased. Chemical and industrial lime was down 10%, construction lime 12%, refractory dolomite 28%, and agricultural lime 11%.

DOMESTIC PRODUCTION

Lime producers sold or used 19.2 million tons, compared with 21.6 million tons in 1974. Sales of lime decreased 12% to 12.9 million tons. Captive lime used by producers declined 10% to 6.3 million tons.

Output of quicklime decreased 12% to 16.8 million tons. Production of hydrated lime decreased 8% to 2.4 million tons. Output of dead-burned dolomite declined 28% and was 62% below the 1956 record high level. The number of plants decreased from 173 to 172 and the average output per plant decreased from 125,100 to 111,400 tons per year.

Eight States—Ohio, Pennsylvania, Texas, Missouri, Michigan, Indiana, Alabama, and Illinois—accounted for 68% of the total output. Production declined 4% in Indiana, 5% in Texas, 6% in Michigan, 7% in Pennsylvania and Alabama, 15% in Illinois, 16% in Missouri, and 17% in Ohio.

W Withheld to avoid disclosing individual company confidential data; included in "Other States."

[1] Excludes regenerated lime. Includes Puerto Rico.

[2] Data may not add to totals shown because of independent rounding.

[3] Includes Idaho, Illinois, Indiana, Iowa, Kentucky, Minnesota, Nevada, New York, North Dakota, Oklahoma, Washington, States indicated by symbol W, and exports.

Leading producing companies were Marblehead Lime Co. with two plants in Illinois and one each in Indiana, Michigan, and Pennsylvania; Mississippi Lime Co. in Missouri; Bethlehem Steel Corp. with two plants in Pennsylvania and one in New York; Allied Chemical Corp. in Louisiana and New York; Martin-Marietta Chemicals in Alabama and Ohio; The Dow Chemical Co. in Michigan and Texas; The Flintkote Co. with two plants in California, two in Nevada, and one each in Arizona, Utah, and Virginia; United States Gypsum Co. in Louisiana, Ohio, and Texas; United States Steel Corp. in Ohio; and Diamond Shamrock Corp. in Ohio. These 10 companies, operating 27 plants, accounted for 40% of the total lime production.

The five largest lime plants, each producing more than 400,000 tons, accounted for 18% of the total lime output. Thirty-three plants produced more than 200,000 tons and accounted for 60% of the total.

Leading individual plants were Mississippi Lime's Ste. Genevieve plant, Marblehead's Buffiington plant, Allied Chemical's Syracuse plant, U.S. Steel's Lorain plant, and Diamond Shamrock's Plainsville plant.

Table 3.—Lime sold or used by producers in the United States, by size of plant[1]

[2] Data do not add to total shown because of independent rounding.

CONSUMPTION AND USES

Lime was consumed in every State. Leading consuming States were Ohio, Pennsylvania, Michigan, Indiana, and Texas, each of which consumed more than 1 million tons. These five States accounted for 53% of the total lime consumed.

Leading quicklime-consuming States were Ohio, Michigan, Indiana, Pennsylvania, and Texas, each of which consumed more than 1 million tons. These five States accounted for 53% of the total quicklime consumed.

Leading hydrate-consuming States were Texas, Pennsylvania, Illinois, Ohio, and Louisiana, each of which consumed more than 100,000 tons. These five States accounted for 56% of the total hydrate consumed.

Lime sold by producers was used for chemicals, 83%; construction, 10%; refractories, 6%; and agriculture, 1%. Captive lime used by producers was 33% of the total, compared with 32% in 1974. Captive lime was used mainly for alkalies, 33%; BOF steel furnaces, 24%; and sugar refining, 13%.

Leading individual uses were BOF steel furnaces, alkalies, water purification, paper and pulp, sugar refining, and refractories, which together accounted for 67% of the total consumption.

Of the main chemical and industrial uses, lime for BOF steel furnaces was produced principally in Ohio (26%), Indiana (16%), Pennsylvania (15%), and Illinois (10%). Lime for alkalies was produced mainly in New York, Michigan, Ohio, and Texas. Lime for water purification was produced mainly in Missouri (29%), Pennsylvania (15%), Texas (9%), and Alabama (8%). Lime used for paper and pulp, excluding regenerated lime, was produced mainly in Alabama (33%), Wisconsin (11%), Texas (11%), and Virginia (11%). Lime for refining sugar was produced mainly in California (23%), Idaho (11%), and Colorado (11%).

[3] Includes magnesia from sea water, magnesite, chrome, lithium, explosives, adhesives, coke, other uses, and uses indicated by symbol W.

PRICES

The average value of lime sold or used by producers in 1975 was $27.46 per ton, an increase of 25% over the 1974 price of $22.02 and an increase of 58% over the 1973 price of $17.42.

Values ranged from $27.00 for chemical and industrial lime to $28.18 for construction lime, $34.13 for refractory dolomite, and $34.75 for lime used in agriculture.

Values for quicklime sold ranged from $27.69 for chemical lime to $30.43 for construction lime, $31.30 for lime used in agriculture, and $33.46 for dead-burned dolomite, and averaged $28.20, an increase of 33% over the 1974 value.

Values for hydrated lime ranged from $27.66 for construction lime to $31.10 for chemical lime, and $36.50 for lime used in agriculture, and averaged $29.52, an increase of 15% over the 1974 price.

FOREIGN TRADE

Exports of lime increased 70% to 53,900 tons but were 22% below the 1968 record. Of the total exports, Canada received 85% and Mexico 8%. The remaining 7% went to 29 countries, listed in order of shipments as follows: The Republic of South Africa, Panama, Trinidad, the Bahamas, Burmuda, the Philippines, West Germany, the United Arab Emirates, Surinam, the United Kingdom, Jamaica, Venezuela, Honduras, Ireland, Colombia, Brazil, Australia, Indonesia, Austria, the Netherlands Antilles, Peru, Bahrain, Argentina, Iran, the Dominican Republic, New Zealand, Singapore, Italy, and Tanzania.

Imports of lime declined 38% to 259,000 tons. Imports were mainly from Canada.

Table 6.—U.S. exports of lime

Year	Quantity (short tons)	Value (thousands)
1973	36,914	$1,208
1974	31,639	1,516
1975	53,853	2,746

1974	48,284	1,311	367,917	6,368	416,201	7,679
1975	44,637	1,392	214,311	4,867	258,948	6,259

WORLD REVIEW

Lime is produced all over the world, mainly in the heavily industralized areas. Source materials are adequate. The United States, with 17% of the total, ranks second in world production.

Canada.—During 1974 there were 24 active lime plants in Canada; 10 in Ontario, 4 in Quebec, 4 in Alberta, 3 in Manitoba, 2 in British Columbia, and 1 in New Brunswick. Of the 85 kilns in operation, 54 were vertical, 27 were rotary, 3 were rotary grate, and 1 was vibratory grate. Total lime output was 1.9 million tons, of which 426,000 tons were exported, mainly to the United States.

Germany, West.—West Germany ranked third in world lime output, with 9% of production. Output was 10.1 million tons.

Japan.—Japan produced 9% of world lime output, and ranked fourth among world producers with 10.1 million tons.

Poland.—Poland produced 8% of the world's lime and ranked fifth among producing countries with 8.8 million tons.

U.S.S.R.—The Soviet Union was the leading lime-producing country in the world, with 21% of the total. Output was estimated at 24 million tons.

Yugoslavia.—Construction started on a new 70,000-ton lime plant at Jelen Do, near Cacak, Serbia. Two new lime plants were completed near Kucevo, Serbia. Construction continued on a new 100,000-ton lime plant near Drnis, Croatia. Plans were made to construct a 120,000-ton lime plant near Slavonski Brod, Croatia.

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] Lime is produced in many other countries besides those listed. Mexico, Venezuela, and the United Kingdom are among the more important countries for which official data are unavailable.

[2] Excludes output by small producers.

[3] Less than ½ unit.

[4] Figure for 1973 includes production in Eritrea.

[5] Year ending June 30 of that stated.

Lithium

By Richard H. Singleton[1]

Total deliveries[2] of lithium minerals[3] in the United States decreased approximately 20% in 1975 to about 4,400 tons of lithium equivalent because of an increase in producers' inventories, and because smaller quantities were released from the Government stockpile. Apparent consumption also decreased by about 20% to approximately 3,500 tons mainly because of decreased demand for lithium carbonate in the aluminum and ceramic industries. Demand for lithium hydroxide monohydrate reportedly remained strong. The United States continued to produce and consume over one-half of the world's lithium supply. Approximately 20% of the U.S. supply continued to be exported to Western Europe and Japan; two-thirds in the form of lithium carbonate with the balance being mainly lithium hydroxide monohydrate.

The United States imported about 4,600 tons of mineral concentrate from Brazil, nearly twice that imported in 1974. Total imports of lithium chemicals by Western Europe increased 13% to approximately 700 tons of lithium equivalent. The share of these imports coming from the United States increased to 86%.

Japanese imports of lithium chemicals decreased by 65% to 237 tons of lithium equivalent reflecting a sharply decreased demand coupled with a reduction of users' inventories during 1975. Total exports of lithium chemicals by the U.S.S.R. to Western Europe and Japan decreased 62% to about 170 tons of lithium equivalent.

Legislation and Government Programs.—The General Services Administration (GSA) sold 371 short tons of lithium hydroxide monohydrate during 1975. At yearend, 2,547 tons of lithium hydroxide monohydrate was available for sale by GSA under the Federal Property Act.

---

[1] Physical scientist, Division of Nonmetallic Minerals.

[2] Deliveries are herein defined as production plus imports minus producers' inventory change.

[3] Spodumene and petalite concentrate. Also includes lithium carbonate from California and Nevada brines.

[e] Estimate. [r] Revised. W Withheld to avoid disclosing individual company confidential data.

[1] Includes lithium carbonate produced in Nevada.

[2] Includes lithium compounds.

DOMESTIC PRODUCTION

The two major lithium producers, Foote Mineral Co. and Lithium Corp. of America (Lithcoa) continued to mine and beneficiate spodumene from pegmatite dikes in North Carolina. Foote, 92%-owned by Newmont Mining Corp., continued as the major domestic producer of spodumene concentrate. Construction continued on its 6,000-ton-per-year lithium carbonate plant in North Carolina, scheduled for completion in 1976. Foote continued to produce lithium carbonate from subsurface brines at Silver Peak, Nev. Kerr-McGee Corp. continued to produce small quantities of lithium carbonate from Searles Lake brines in California.

Lithcoa remained the major producer of lithium chemicals, excluding lithium carbonate, at its North Carolina works near its mine. Beneficiation capacity for producing spodumene concentrate was increased 20% in 1975. Lithcoa also increased its lithium hydroxide production capacity by 20%.

CONSUMPTION AND USES

Apparent domestic consumption in 1975 decreased 20%, compared with 1974, although consumption continued to increase during the first calendar quarter. Lithium carbonate sales were down because of reduced demand in the aluminum and ceramic and glass industries, which were the major consumers of lithium products.

Reduced demand in the aluminum industry was primarily due to lowered production of primary aluminum; interest in this use of lithium remained high, and several major world aluminum producers initiated potline tests in 1975. Aluminum Co. of America at Palestine, Tex., began operation in 1975 of a 15,000-ton-per-year aluminum potline using a new type of reduction cell based on the electrolysis of aluminum chloride and using lithium chloride as a component of the electrolyte.

Demand was down in 1975 for lithium fluoride, used principally in the ceramics industry, and for lithium chloride, used in welding and dehumidification. Demand for lithium bromide, used in air conditioning, decreased less than that for the other two halides. Demand for lithium in grease, synthetic rubber, and vitamin A manufacture held steady at about the same level as in 1974. Demand for lithium hydroxide increased.

PRICES

The domestic price of ceramic-grade spodumene concentrate remained steady throughout 1975 at $123.50 per ton as reported in Ceramic Industry. The domestic price of lithium carbonate powder delivered, bagged, and in carload lots remained steady at 79.5 cents per pound during 1975 as reported in Chemical Marketing Reporter. Prices of both the hydroxide and the metal held steady during the first half of 1975. The price of lithium hydroxide monohydrate delivered in drums, carload lots, increased 35% to $1.18 per pound at yearend. The price of lithium metal delivered in lots of 1,000-pounds minimum rose 18% to $11.10 per pound at yearend.

FOREIGN TRADE

U.S. exports of lithium chemicals are not completely reported in available trade statistics, with some of the compounds included inseparably with other nonlithium-bearing compounds. However, review of data on imports of lithium compounds from the United States by other countries indicates that, in terms of lithium content, exports decreased by approximately 10%; lithium carbonate accounted for about two-thirds of these exports in 1975, the remainder being largely lithium hydroxide. Japan, West Germany, and France received 90% of apparent U.S. exports of

Table 2.—Lithium metal and chemicals: Apparent U.S. exports[1] to selected countries

[r] Revised. NA Not available.

[1] Only in the case of lithium hydroxide are U.S. exports of lithium chemicals reported separately in official U.S. trade statistics. Other lithium compounds as well as lithium metal are reported in basket categories. Data in this table are derived from import statistics of the listed major trading partner countries.

[2] Officially recorded U.S. exports totaled 599 short tons, distributed as follows: Argentina—5, Belgium-Luxembourg—2, Bolivia—2, Brazil—2, Canada—23, France—124, West Germany—55, India—2, Indonesia—6, Italy—20, Japan—181, the Republic of Korea—1, Mexico—21, the Netherlands—56, Romania—5, Spain—36, Sweden—less than ½ unit, and the United Kingdom—58.

[3] Less than ½ unit.

[4] Figure represents estimated gross weight of lithium bromide included in a basket category of lithium bromide plus potassium bromide (50% of total reported lithium bromide and potassium bromide is assumed to be lithium bromide).

[5] Officially recorded U.S. exports total 613 short tons, distributed as follows: Belgium-Luxembourg—15, Bolivia—12, Brazil—2, Canada—25, Chile—9, France—142, West Germany—33, India—29, Indonesia—42, Iran—2, Ireland—2, Japan—117, Mexico—54, the Netherlands—49, Pakistan—3, Philippines—2, the Republic of South Africa—11, Spain—11, Sweden—5, Switzerland—8, Thailand—5, and the United Kingdom—35.

lithium products. Apparent exports to Japan decreased 56%. Apparent exports to West Germany increased 36%. Approximately 600 tons of spodumene concentrate, equal to about 22 tons of lithium equivalent, was shipped to West Germany, France, and the Netherlands, a decrease of 83% from 1974, according to recipient-country import data.

Imports of lithium-mineral concentrate were 44% above the 1974 level at 4,548 tons, containing about 80 tons of lithium. Brazil supplied all of these imports primarily as hand-picked petalite for use in low-expansion ceramicware.

Buffalo: Canada	786	106	--	--
Total	3,165	323	4,548	538

WORLD REVIEW

Canada.—Construction of a commercial mine and plant at Bernic Lake in Manitoba for producing lithium carbonate, announced in 1974 for completion in 1977, had not begun by the end of 1975, and $20 million in investment capital was being sought by the potential producer, Tantalum Mining Corp. of Canada, Ltd. However, construction of a pilot plant at Bernic Lake for production of lithium carbonate began. The plant reportedly will process 100 tons of spodumene ore per day. Scattered prospecting for lithium minerals continued in Ontario. No exports of lithium minerals from Canada were apparent.

Chile.—Preliminary exploration aided by the U.S. Geological Survey indicated the presence of more than 1 million tons of lithium equivalent in the subsurface potassic brines in Salar de Atacama. The reported lithium concentration is greater than 0.1%, and commercial exploitation appeared feasible. The Salar de Uyuni in neighboring Bolivia appeared favorable geologically for similar accumulation of large amounts of lithium-rich brines.

France.—Imports of lithium chemicals decreased 15% to 158 tons of lithium equivalent. Imports of lithium mineral concentrate decreased about 71% to about 40 tons of lithium equivalent.

Germany, West.—Imports of lithium chemicals into West Germany, Europe's largest producer of secondary lithium salts, increased 15% to about 550 tons of lithium equivalent, mainly because of increased receipts of lithium carbonate from the United States. Imports of lithium mineral concentrate decreased 17% to about 90 tons of lithium equivalent. Approximately 30% of these imports were reexported after chemical processing mainly to other countries in West Europe.

Japan.—Imports of lithium chemicals into Japan decreased greatly, by 65%, to 237 tons of lithium equivalent. This was due to lowering of consumer inventories that had been accumulated in 1974 and a marked decrease in demand for lithium bromide in air conditioning. Markets were sought for Japanese air conditioning systems in Southeast Asia and the Middle East. Significant quantities of lithium mineral concentrates were imported, but tonnages were not available because they were included inseparably with other nonlithium-bearing minerals.

Mozambique.—Exports of lithium mineral concentrate, all to Western Europe, decreased 83% to about 2,300 tons in 1975. No concentrate was produced in Mozambique.

South Africa, Republic of, and Territory of South-West Africa.—No concentrate was produced in South Africa in 1975. Approximately 35,000 tons of concentrate was exported to the United Kingdom in 1974.

U.S.S.R.—Exports of lithium chemicals to Western Europe and Japan in 1975 were about 64% below those of 1974.

United Kingdom.—Associated Lead Manufactures Ltd., the only manufacturer of lithium chemicals in the United Kingdom, announced in 1975 that it was going out of the lithium chemical business, based on the loss of Rhodesian petalite as a raw material source for production.

Zaire.—Discovery of a zoned pegmatite near Manono, representing perhaps the largest lithium resource in the world and estimated to contain in excess of 1 million tons of lithium equivalent, was announced. A 5,000-ton-per-year lithium carbonate plant was planned, but financing was not arranged and no schedule was given.

[e] Estimate. [p] Preliminary. [r] Revised. W Withheld to avoid disclosing individual company confidential information.

[1] In addition to the countries listed, other nations may produce small quantities of lithium minerals but output is not reported and no valid basis is available for estimating production levels.

[2] Figures presented are U.S. imports from Canada; official Canadian sources report no production since 1965, but the United States has imported lithium materials from Canada in most years since that time. It is not clear whether these imports are from: (1) accumulated stocks; (2) test production quantities not reported in official Canadian statistics; (3) Canadian imports; or (4) any combination of these sources.

[3] These estimates denote only an approximate order of magnitude; no basis for more exacting estimates is available. Output by China and the U.S.S.R. have never been reported; Southern Rhodesian output has not been reported since 1964.

[4] Output has not been officially reported since 1966, but presumably has continued since a number of countries record imports from "South Africa" which in total quantity considerably exceed reported output by the Republic of South Africa proper, and presumably include shipments from South-West Africa. Quantities given represent imports by the United States and the European Community reported as originating in South Africa, but the reader is cautioned that a portion of this material may have been mined in Southern Rhodesia. In 1966, actual output from South-West Africa totaled 1,739 short tons including: amblygonite—30; lepidolite—365; petalite—1,344.

[1] Compiled from import statistics of listed importing countries except where otherwise noted. Conversion from reported metric tons to short tons was accomplished by multiplying metric tons by 1.10231. Conversions to lithium content from reported gross weights were accomplished through the use of the following conversion factors: Lithium carbonate—multiply by 0.188; lithium hydroxide—multiply by 0.165; lithium chloride—multiply by 0.164; lithium bromide—multiply by 0.080. It should be noted that most of the reporting countries provide data for a basket category of "lithium oxide and hydroxide"; this has been assumed to be largely, if not entirely, the monohydrate form of lithium hydroxide ($LiOH \cdot H_2O$) and the factor selected for converting gross weight of this material to lithium content is based on this assumption.

[2] Source: West German official export statistics.

[3] Less than ½ unit.

[4] Source publication reports imports of the total of lithium bromide and potassium bromide as a single figure; entry here is an estimate based on the assumption that half of the total is lithium bromide.

[5] Receipts, of any, from this source are not reported separately, but are included in other.

[6] Totals are of listed figures only except where otherwise indicated; as such, they are only partial totals in most cases.

TECHNOLOGY

Studies[4] at North Carolina State University on recovery of spodumene ore by froth flotation resulted in adoption of ball mill grinding on a commercial scale in the North Carolina spodumene industry. Prior to 1973, rod milling had been used exclusively in this industry.

Argonne National Laboratory continued development of a rechargeable lithium cell for automotive and energy-storage use. This lithium-sulfur cell has a solid lithium-aluminum alloy anode, an iron sulfide cathode (either FeS or FeS_2), a molten LiCl-LiF eutectic electrolyte, and a cell chamber separator made of boron nitride fabric. The cell operates at between 380° and 450° C, has a specific energy five times that of a lead-acid storage cell, and operates at a 1.5-volt output. Cell-life goal was 8 years. In 1975, cell life of 5 months was attained and this included several hundred charge-discharge cycles. A major effort to lower cell fabrication cost is continuing.

Eagle-Picher Industries, Inc., announced a plan to build the first privately owned and operated commercial facility in the United States for production of Li_7 isotope for the nuclear power industry. Operation was expected by 1977. Lithium is used to control the pH level in primary cooling systems of pressurized water reactors. Impact on the lithium industry was considered to be negligible since the total lithium requirement would not be more than about 1 ton per year.

Magnesium

By Benjamin Petkof [1]

World production of primary magnesium metal was slightly lower than that of 1974. Domestic primary metal production remained strong but declined from that of 1974. A significant quantity of secondary magnesium was also produced. Exports declined but imports increased. The quoted price of magnesium metal was higher than that of 1974 but was stable during the entire year.

[1] Excludes United States production.

Legislation and Government Programs.—The General Services Administration strategic and critical stockpile contained 1,621 tons of magnesium at yearend 1975. There were no stockpile releases or accessions during the year.

DOMESTIC PRODUCTION

Magnesium ingot producers during 1975 were American Magnesium Co., Snyder, Tex., with an annual capacity of 10,000 short tons; The Dow Chemical Co., Freeport, Tex., with an annual production capacity of 120,000 short tons; and NL Industries, Inc., Rowley, Utah, with an annual capacity of 45,000 short tons. The electrolytic method was used by all domestic producers. Publication of Bureau of Mines data on domestic production is withheld to avoid disclosing individual company confidential data.

Northwest Alloys, Inc., a wholly-owned subsidiary of the Aluminum Co. of America (Alcoa) continued construction of its magnesium facilities at Addy, Wash. The facility was expected to commence operation in 1976 The future output of this plant will be utilized by Alcoa for production of aluminum alloys. Planned initial production capacity was 24,000 tons per year.

CONSUMPTION AND USES

Following the general economic decline, domestic magnesium consumption in 1975 dropped 27% below that of 1974 to 94,815 tons. Magnesium was consumed in structural products that included castings and wrought products, and in sacrificial purposes where advantage was taken of the metal's chemical and alloying properties. The metal's useful structural properties such as low specific weight, good machinability, hot formability, and high strength-to-weight ratio resulted in about 21% of consumption being used for structural applications in aircraft, automotive, and other types of transportation equipment, materials handling equipment, and the manufacture of items such as power tools. The remainder was used for sacrificial purposes, primarily alloying with other metals (49%), cathodic protection (5%), production of nodular iron (14%), and reducing agents for metals such as titanium, zirconium, hafnium, uranium, and beryllium (7%).

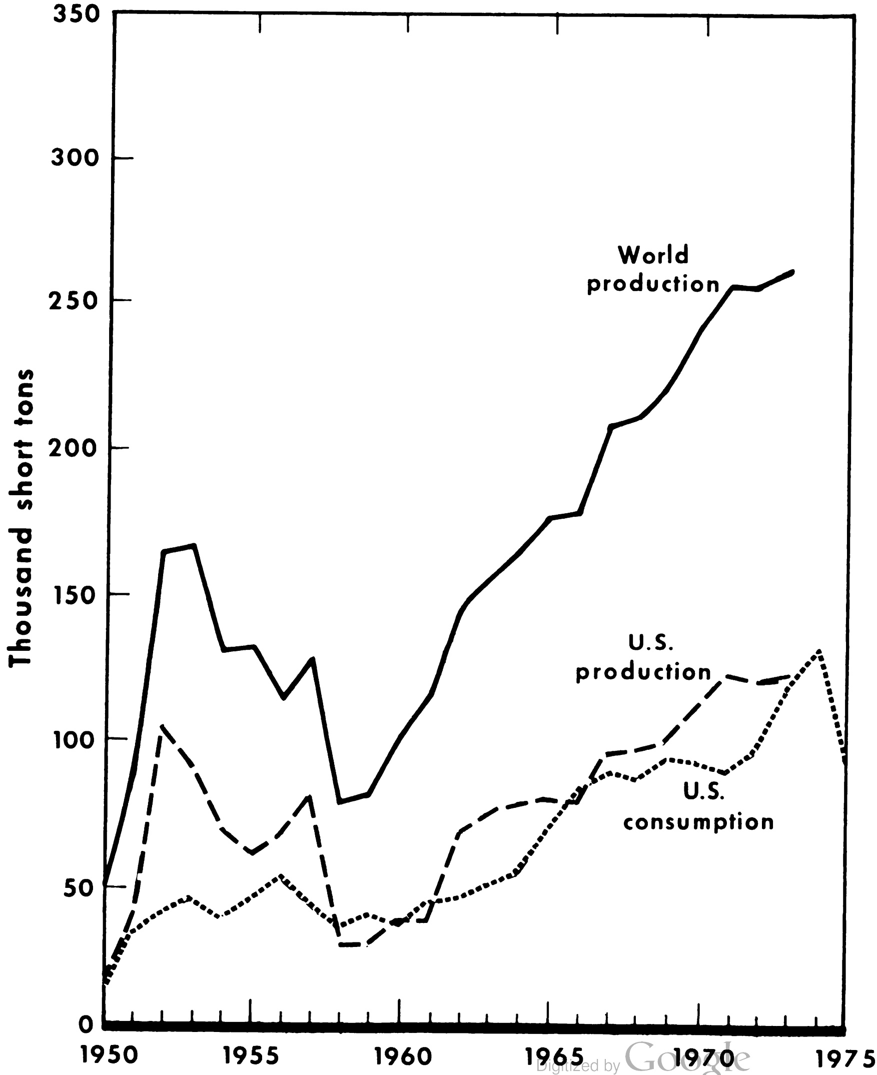

Figure 1.—U.S. and world production and U.S. consumption of primary magnesium

PRICES

The base price of magnesium ingot was stable during 1975 and was quoted at $0.82 per pound for 99.8% purity metal, minimum 10,000-pound lots, f.o.b. plant. As of January 1, 1976, the quoted price increased by $0.05 to $0.87 per pound.

STOCKS

Producer and consumer stocks of primary magnesium declined 7% to 19,664 tons at yearend 1975. Yearend stocks of primary magnesium alloy ingot dropped 10% to 1,512 tons. Stocks of primary metal at yearend 1974 were 21,106 tons, and those of alloy ingot 1,677 tons. New and old magnesium scrap stocks declined 39%.

Total	1,303	6,036	1,065	5,475	6,540	799

r Revised.

[1] Includes borings, turnings, drosses, etc.

FOREIGN TRADE

The quantity of magnesium exported declined 30% from 46,398 tons in 1974 to 32,591 tons in 1975. However, the value declined only slightly from $48.5 million in 1974 to $48.2 million in 1975. Shipments to Brazil, Canada, West Germany, Japan, Mexico, and the Netherlands represented 92% of the total. Almost all the magnesium exported (95%) consisted of primary metal and alloys.

Total magnesium imports for consumption increased 49% from 5,305 tons valued at $5.2 million in 1974 to 7,903 tons valued at $11.5 million in 1975. Imports of metal accounted for 61% of total imports; waste and scrap 25%; and alloys and other forms, 14%. Major sources of magnesium imports were: Canada (21%); Norway (25%); and Japan (22%).

WORLD REVIEW

World magnesium production (excluding U.S. production) declined from 144,686 tons in 1974 to 141,980 tons in 1975. The U.S.S.R. produced 49% of the world magnesium output (excluding U.S. production) followed by Norway (30%); Japan (7%); and France (6%). The remainder was supplied by Canada, the People's Republic of China, and Italy.

Table 7.—Magnesium: World production,[1] by country
(Short tons)

Country	1973	1974	1975 p
Canada	6,840	6,566	4,961
China, People's Republic of e	1,100	1,100	1,100
France	r 7,710	7,199	8,307
Italy	9,850	10,119	6,998

Total	r 264,647	[4] 144,686	[4] 141,980

e Estimate. p Preliminary. r Revised. W Withheld to avoid disclosing individual company confidential data.
[1] Primary only.
[2] Secondary production was as follows in short tons: 1973—8,936; 1974—11,990; and 1975 (preliminary)—10,171.
[3] Dow Chemical Company only.
[4] Excludes United States production, which in previous years accounted for approximately 50% of the total.

Canada.—Chromasco Ltd. was the only primary metal producer and has operated a mine and smelter at Haley, Ontario, since 1942 using the silicothermic process. Canada consumed 6,853 tons of metal in 1974 with the major portion used by the aluminum industry. The casting industry also consumed a significant quantity of the metal. Canada imported 6,886 tons and exported 3,521 tons of magnesium metal in 1974.

Japan.—About 18,000 tons of both primary and secondary magnesium metal were produced in 1975. Imports and exports amounted to 4,563 tons and 2,549 tons, respectively. Consumption (probably both primary and secondary) was 20,193 tons of magnesium metal for uses such as reducing titanium and zirconium in smelting plants, production of aluminum-magnesium alloys, and manufacture of rolled products, casting nodular cast iron, magnesium powder, and cathodic protection anodes.[2]

Yugoslavia.—A new installation for production of magnesium metal may be built near Boljevac na Ibru. Details about size and cost were not made public.

TECHNOLOGY

The National Research Council published a review of magnesium metal usage and future trends.[3]

The basic Alcan-type magnesium cell was modified to improve operation and magnesium metal recovery from magnesium chloride which is generated in producing titanium.[4]

The problem of recycling automotive scrap was reviewed. Methods for scrap processing and separation of individual metals such as aluminum and magnesium were discussed and evaluated.[5]

New equipment was developed for producing ductile iron. The equipment has a cylindrical ladle for hot metal that incorporates a plunger through which a magnesium additive flows. It was claimed that use of this equipment recovers about 70% of magnesium metal.[6]

[5] Lockwood, L. F. Magnesium: A Recyclable Automotive Material. Proc., 32d Ann. Meeting, Internat. Magnesium Assoc. Dearborn, Mich., May 18–21, 1975, pp. 31–39.

Factors such as alloy selection, storage, size, and ladle design to improve the efficiency of magnesium in producing ductile iron were described.[7]

A method was developed to produce magnesium from dolomite. Calcined dolomite was mixed with silicon or ferrosilicon, briquetted, and heated to a temperature of 1,050° to 1,200° C in an inert atmosphere and under optimum pressure. Vaporization of the magnesium formed in this step was inhibited and calcium-silicon alloy was formed within the briquettes. The magnesium in the briquettes was recovered by melting in an internally heated furnace.[8]

Magnesium Compounds

By Benjamin Petkof[1]

World magnesite production remained strong during 1975 with Austria, Greece, the U.S.S.R., the People's Republic of China, and North Korea providing about three-fourths of world output. However, refractory magnesia and caustic-calcined and specified magnesias, sold or used by domestic producers in 1975, declined in both quantity and value.

Exports of magnesite and magnesia totaled 91,752 tons, an increase of 48% above that of 1974. The bulk of shipments were destined to Canada, West Germany, Mexico, and Austria. Imports for consumption of processed magnesite were almost unchanged from those of 1974.

r Revised.
[1] Excludes caustic-calcined magnesia used in production of refractory magnesia.
[2] Caustic-calcined magnesia only.

DOMESTIC PRODUCTION

Barcroft Co., The Dow Chemical Co., Harbison-Walker Refractories, Kaiser Aluminum & Chemical Corp., Merck & Co., Inc., and Michigan Chemical Corp. produced magnesium hydroxide from seawater and well brines. The magnesium hydroxide was used primarily to produce magnesia for basic refractories. Producers of refractory magnesia were Basic, Inc., Basic Magnesia, Inc., Cohart Refractories Co., Inc., A. P. Green Refractories, Co., Harbison-Walker Refractories, Kaiser Aluminum & Chemical Corp., and Martin-Marietta Chemicals. Total production of refractory magnesia in 1975 was 722,554 tons.

Caustic-calcined magnesia was produced by Basic, Inc., Basic Magnesia, Inc., The Dow Chemical Co., Kaiser Aluminum & Chemical Corp., Martin Marietta Chemicals, and Michigan Chemical Corp. Total production of caustic-calcined magnesia was 165,380 tons. Merck & Co., Inc., Michigan Chemical Corp., and Morton Chemical Co. produced 10,183 tons of specified magnesia. The Dow Chemical Co., Mallinckrodt Chemical Works, and Philadelphia Quartz Co. produced hydrous and anhydrous magnesium sulfate. Magnesium carbonate was produced by Mallinckrodt Chemical Works, Merck & Co., Inc., Michigan Chemical Corp., and Morton Chemical Co.

---

[1] Physical scientist, Division of Nonferrous Metals.

Magnesium chloride was produced by American Magnesium Co., The Dow Chemical Co., FMC Corp., Great Salt Lake Minerals & Chemicals Corp., and Kaiser Aluminum & Chemical Corp. Most of the magnesium chloride production was used to produce magnesium metal.

Domestic producers of magnesium compounds by raw material source, location, and capacity follow:

Raw material source and producing company	Location	Capacity (short ton of MgO equivalent)
Magnesite: Basic, Inc	Gabbs, Nev	150,000
Lake brines:		
Great Salt Lake Minerals & Chemicals Corp	Ogden, Utah	100,000
Kaiser Aluminum & Chemical Corp	Wendover, Utah	50,000
Well brines:		
The Dow Chemical Co	Ludington, Mich	250,000
Martin Marietta Chemicals	Manistee, Mich	280,000
Michigan Chemical Corp	St. Louis, Mich	25,000
Morton Chemical Co	Manistee, Mich	5,000
Seawater:		
Barcroft Co	Lewes, Del	5,000
Basic Magnesia, Inc	Port St. Joe, Fla	100,000
Cohart Refractories Co	Pascagoula, Miss	40,000
The Dow Chemical Co	Freeport, Tex	100,000
FMC Corp	Chula Vista, Calif	5,000
Harbison-Walker Refractories Co	Cape May, N.J	100,000
Kaiser Aluminum & Chemical Corp	Moss Landing, Calif	150,000
Merck & Co., Inc	South San Francisco, Calif	10,000
Total		1,370,000

CONSUMPTION AND USES

Domestic use of almost all magnesium compounds declined in 1975, following the general pattern of decreased domestic economic activity. The major end use for magnesia continued to be the manufacture of refractories. Refractory magnesia consumption declined 12% in quantity but increased 35% in value from that of 1974. The consumption of caustic calcined and specified magnesia declined 20%; magnesium hydroxide 35%; magnesium sulfate 38%. Magnesium carbonate consumption increased 18%.

The quantity of caustic-calcined magnesias used for the manufacture of agricultural, nutritional, and pharmaceutical products decreased 1%; construction materials decreased 4%; chemical processing, manufacturing, and metallurgical decreased 23%.

Magnesia had a wide area of use including the production of animal feed, fertilizers and pharmaceuticals, and other chemical processing and manufacturing applications.

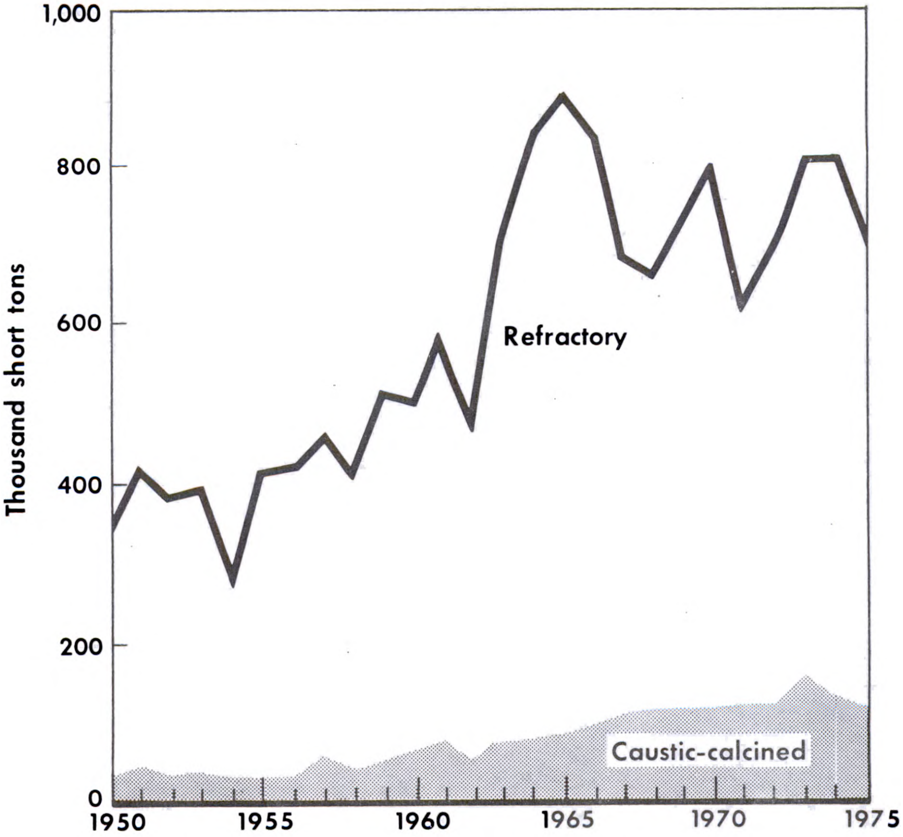

Figure 1.—Consumption and shipments of magnesia in the United States.

PRICES

The prices for magnesia, natural, technical, heavy, 85% and 90% (bulk, carlot and truckload, f.o.b. Luning, Nev.) were quoted at yearend at $85 and $105 per short ton, respectively, according to the Chemical Marketing Reporter. Magnesia, technical, neoprene-grade, light, was quoted at $346 per ton (bags, carlot and truckload, works).

Prices throughout the year for magnesium carbonate, technical (bags, carlot, freight-equalized) were quoted at $0.22 to $0.23 per pound, and NF grade, $0.30 to $0.31 per pound. During the year, the price for magnesium hydroxide, NF, powder, (drums, carlot and truckload, works) was $0.35 to $0.36 per pound. Magnesium chloride, hydrous, 99%, flakes (bags, carlot, works) was quoted at $120 per ton.

The price for magnesium sulfate, technical (bags, mixed carlot, 10,000-pound minimum, works) was quoted at $0.06 per pound.

FOREIGN TRADE

Exports of dead-burned magnesite and magnesia totaled 82,654 tons, valued at \$14.1 million, an increase of 61% in quantity, and 83% in value. Shipments to Canada increased 22% from those of 1974 and represented 59% of total material exported. Significant quantities were also exported to West Germany (18%), Mexico (9%), Austria (5%), the Republic of South Africa (4%), and Chile (2%).

Exports of magnesite, including crude, caustic-calcined, lump or ground, declined 15% in quantity and 11% in value from those of 1974. Shipments to Canada, Yugoslavia, the Netherlands, and West Germany accounted for 70% of exports in this category.

Imports of lump, ground, caustic-calcined magnesias declined 43% to 5,716 tons in 1975. Most of the imports were received from India (75%), Australia (12%), Turkey (10%), and the Netherlands (3%). Imports of dead-burned and grain magnesia and periclase containing a maximum of 4% lime decreased from 131,978 tons in 1974 to 125,540 tons in 1975, a decline of 5%. Imports of the same material, but containing over 4% lime, rose 26% from 24,423 tons in 1974 to 30,792 tons in 1975. Total imports of crude and processed magnesite declined 2%, from 165,391 tons in 1974 to 162,048 tons in 1975.

Imports of specified magnesium compounds and compounds not specifically provided for were valued at \$1,793,000.

[1] In addition, magnesium carbonate not precipitated, was imported in 1973—5 short tons ($1,436), 1974—19 short tons ($6,961), 1975—6 short tons ($2,226).

[2] Not specifically provided for; includes magnesium silicofluoride or fluosilicate and calcined magnesium.

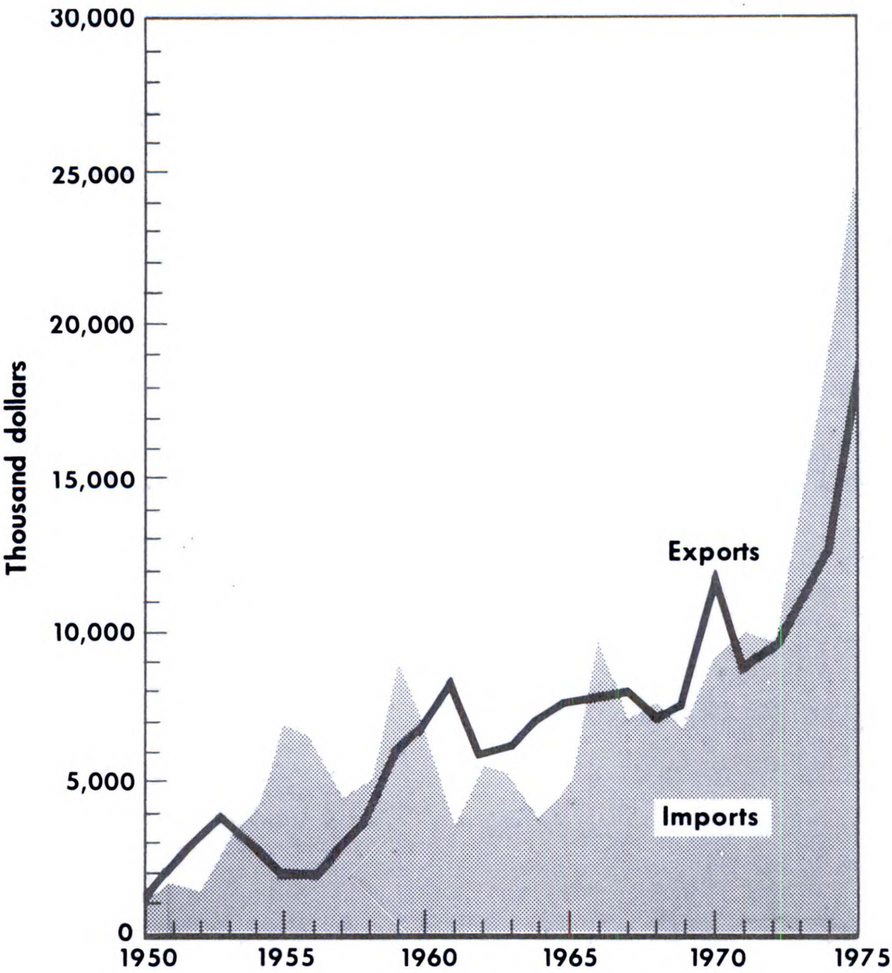

Figure 2.—Value of U.S. exports and imports of magnesia.

WORLD REVIEW

Greece.—The nation retained its status as a major world producer of crude and dead-burned magnesite. Exports of crude and dead-burned magnesite were 26,240 tons, valued at $1.2 million, and 407,925 tons, valued at $66 million, respectively.

The Financial Mining-Industrial & Shipping Corp. (FIMISCO) moved forward with a program for expansion, automation, and diversification of its refractories manufacturing activities which included the production of new types of refractory brick, installation of a tar impregnation unit, acquisition of a manufacturing license from the U.S. firm George P. Reintjes, Co., Inc., for special electric furnace roofs, and expansion and improvement of its ore-dressing facilities. FIMISCO anticipates completion of a new flotation plant to beneficiate low-grade magnesite and wastes in 1976 and a 50,000-ton-per-year vertical kiln for calcining bricks fabricated from flotation concentrates by 1979.

[e] Estimate. [p] Preliminary. [r] Revised. W Withheld to avoid disclosing individual company confidential data; not included in total.

[1] Figures represent crude salable magnesite. In addition to the countries listed, Bulgaria and Canada produce magnesite, but output is not reported and available information is inadequate to make reliable estimate of output levels.

[2] Year beginning March 21 of that stated.

In September 1975, the Government gave FIMISCO authorization for construction of a $50 million plant to recover magnesia from seawater and dolomite on Euboea. Initial annual plant capacity was planned for 100,000 tons of refractory-grade magnesia with a planned future expansion to 200,000 tons. Plant construction was expected to begin in 1976 and be completed in 1979. By 1979 FIMISCO was expected to diversify its refractory production to include tar-bonded dolomite and magnesite-dolomite brick and fired dolomite brick.

Macedonian Magnesite Mining-Industrial and Shipping Corp. planned construction of a third 70,000-ton-per-year-capacity rotary kiln. Magnomin General Mining Co., S.A. (subsidiary of General Refractories) began a $12 million investment program to increase its dead-burned magnesite capacity from 50,000 tons to 120,000 tons annually, and to produce about 22,000 cubic yards of insulating board from low-grade caustic-calcined magnesite by 1982.

Grecian Magnesite Ltd. was expanding and improving its mining, ore dressing, and sintering facilities at Gerakini, Chalkidiki, by installing a new rotary kiln and automatic ore sorters to increase production of caustic-calcined and dead-burned magnesite. Magnesite Mining Industrial and Commercial S.A. continued development of the Troupi mine in North Euboea and began installation of a rotary kiln for dead-burned magnesite and ore-dressing facilities for concentrates. Operation was expected to begin in mid-1976.

Pakistan.—Good-quality magnesite ore was produced from small mines in Baluchistan's Zhob District and near Abbottãbã in the North West Frontier Province. The People's Republic of China (PRC) has conducted tests with ore from these mines and found it suitable for refractory brick manufacture. PRC technicians were preparing initial designs for a plant with a production capacity of 15,000 tons of brick per year.

Turkey.—Total reserves of magnesite were estimated at about 17 million tons.

Major deposits were located in Eskisehir, Konya, Denizli, Sivas, Erzincan, Kütahya, Mugla, and Bursa.

Yugoslavia.—The first Yugoslav plant for production of sintered magnesia from seawater was scheduled to be built at Bar, Montenegro. Magnochrome, the largest processor of magnesite in the country, will cover construction costs of about $570,000. The initial annual capacity will be 100,000 tons of sintered magnesia. Employment was expected to be 300 persons.

Seawater magnesia production facilities and capacities throughout the world by country follow:

Country	Location	Company	Capacity (short tons of MgO)
Canada	Aguathuna, Newfoundland	Lundrigan's Ltd	30,000
Ireland	Dungarvan, Waterford	Pfizer Chemical Corp	75,000
Israel	Arad	Dead Sea Works, Ltd	50,000
Italy	Syracuse, Sicily	Compagnia Generale de Magnesio S.p.A.	60,000

TECHNOLOGY

A potential improvement in the operation of lime and limestone wet industrial scrubbers that requires modification of the scrubber solution chemistry was reported. A more reactive limestone (or lime) slurry was created by the addition of a major amount of soluble sulfate such as magnesium sulfate.[2]

Crushed magnesite ore associated with serpentine was treated with small quantities of diesel oil and cationic collector to activate the surfaces of the serpentine and other gangue minerals. Finely divided magnetite or ferrosilicon was added to the conditioned ore to increase the magnetic susceptibility of the gangue minerals. Application of magnetic separation provided a nonmagnetic magnesite fraction and a magnetic gangue fraction.[3]

Manganese

By Gilbert L. DeHuff [1]

Cuts in steel production at home and abroad resulted in substantially lower consumption of manganese alloys and metal in 1975. Although domestic consumption of manganese ore decreased somewhat, production of ferromanganese increased over that of 1974 owing to resumption of production by one of the country's two blast furnace producers of standard high-carbon alloy. Ferromanganese imports continued at a high level, but prices of the imported alloy dropped appreciably during the year. The General Services Administration (GSA) continued its sales of manganese ore surplus to the stockpile objective. There was neither production nor shipment of manganese ore, concentrate, or nodules, containing 35% or more manganese, in the United States in 1975.

Legislation and Government Programs.—Total Government sales of manganese stockpile excesses for the calendar year, as reported by GSA, were as follows in short tons (gross weight): Natural battery ore of stockpile grade, 43,694; synthetic dioxide, 50; type B chemical ore, 18,000; and metallurgical ore, 63,826 of stockpile grade and 409,991 of nonstockpile grade.

Government stockpile physical inventory changes for manganese items in calendar year 1975 consisted of the following: Stockpile-grade natural battery ore decreased 1,379 short tons to 252,072 tons; synthetic dioxide decreased 2,300 tons to 5,838 tons; type B chemical ore decreased 4,497 tons to 95,000 tons; metallurgical ore, stockpile grade, decreased 588,726 tons to 5,614,412 tons; metallurgical ore, nonstockpile grade, dropped 27,235 tons to 1,340,716 tons; high-carbon ferromanganese was down 54,566 tons to 607,478 tons; and electrolytic metal decreased by 25 tons to 14,171 tons.

DOMESTIC PRODUCTION

For the second year in succession, there was neither production nor shipment of manganese ore, concentrate, or nodules, containing 35% or more manganese, in the United States. Ferruginous manganese ore containing 10% to 35% manganese was produced and shipped in New Mexico, and shipments continued from mine or mill stockpiles on the Cuyuna Range of Minnesota. Total shipments decreased 42% from those reported for 1974. No manganiferous iron ore containing 5% to 10% manganese was produced or shipped in either 1975 or 1974. Manganiferous zinc residuum continued to be recovered from New Jersey zinc ores.

Table 2.—Manganese and manganiferous ore shipped[1] in the United States, by State
(Short tons)

Type and State	1974		1975	
	Gross weight	Manganese content	Gross weight	Manganese content
Manganese ore (35% or more Mn, natural)	--	--	--	--
Manganiferous ore: Ferruginous manganese ore (10% to 35% Mn, natural):				
Minnesota	225,560	28,744	108,749	12,880
New Mexico	47,348	6,060	49,976	5,696
Total[2]	272,908	34,804	158,725	18,576
Value manganese and manganiferous ore	$2,328,254	--	$1,411,912	--

[1] Shipments are used as the measure of manganese production for compiling U.S. mineral production value. They are taken at the point at which the material is considered to be in marketable form for the consumer. Besides direct-shipping ore, they include, without duplication, concentrate and nodules made from domestic ores.

[2] There were no shipments of manganiferous iron ore containing 5% to 10% Mn, natural.

CONSUMPTION, USES, AND STOCKS

In the production of raw steel (ingots, continuous- or pressure-cast blooms, billets, slabs, etc., and including steel castings), consumption of manganese as ferroalloys, metal, and direct-charged ore, as reported to the Bureau of Mines by consumers, was 13.3 pounds per short ton of raw steel produced. Of this total, 11.4 pounds was ferromanganese; 1.6 pounds, silicomanganese; 0.03 pounds, spiegeleisen; 0.2 pound, manganese metal; and 0.02 pound, manganese ore (containing 35% or more manganese). The comparable 1974 total, on the same basis, was 13.3 pounds with ferromanganese at 11.5, silicomanganese at 1.4, spiegeleisen at 0.05, metal at 0.25, and ore at 0.1. In addition to the aforementioned consumption of manganese in 1975, there was consumed per short ton of raw steel produced approximately 1.3 pounds of manganese contained in manganese ore used in making pig iron or equivalent hot metal. The comparable figures for 1974 and 1973 were 1.2 and 1.1 pounds, respectively.

Producers of manganese ferroalloys and metal were caught between rising costs and competition from imports on the one hand and a lessened demand at stable or lower product prices on the other. A sharp drop in steel production was primarily responsible for the low demand, but aluminum and other markets were off along with the general economy. Pursuit of ongoing pollution control programs continued to add to both capital and operating costs, and rising energy costs made conservation of energy a matter for attention. Plant modernization looked forward to expected high demand in the not too distant future, and there was some conversion of furnaces from chrome to manganese alloy products.

Union Carbide Corp. early in the year consolidated its Ferroalloys Div. and its Mining and Metals Div. into a new Metals Div.

Table 3.—Consumption and industry stocks of manganese ore[1] in the United States

W Withheld to avoid disclosing individual company confidential data, included in "Miscellaneous and unspecified" where applicable.

[1] Virtually all electrolytic.

Electrolytic Manganese Metal.—All of the manganese metal produced domestically, and virtually all of that imported, was electrolytic metal. Virtually all of the metal consumed was electrolytic metal, but it appears that some low-carbon ferromanganese (such as "Massive Manganese" or "Gimel Metal") and some manganese-aluminum additives were erroneously reported by consumers as manganese metal. The metal that was used to make manganese-aluminum additives is included in table 4 under the "Alloys (excludes alloy steels and superalloys)" category. The additives are not knowingly included in the table, it being desired to report consumption at the metal rather than the additive level of the usage cycle.

The supply situation with respect to electrolytic manganese metal changed from one of shortage in 1974 to one of oversupply in 1975, necessitating severe production cuts. Production of electrolytic metal dropped appreciably to 22,141 short tons from 27,033 tons in 1974. Production was by the same three plants of the same three companies: Foote Mineral Co., New Johnsonville, Tenn.; Kerr-McGee Chemical Corp., Hamilton (Aberdeen), Miss.; and Union Carbide Corp., Marietta, Ohio. With completion of Kerr-McGee's expansion of productive capacity to 9,300 tons of metal per year, and an increase of about 10% in Foote's annual capacity to approximately 11,000 tons, total U.S. annual capacity was approximately 30,000 tons by midyear.

Ferromanganese.—Bethlehem Steel Corp., at Johnstown, Pa., and United States Steel Corp., at McKeesport, Pa., were the only domestic ferromanganese producers using blast furnaces. United States Steel resumed production at McKeesport in May after having sacrificed ferromanganese production for pig iron for a year or more previously. Electric furnaces were used to produce ferromanganese by six companies in eight plants: Airco Alloys Div., Airco Inc., Calvert City, Ky.; Ohio Ferro-Alloys Corp., Philo, Ohio; Roane Electric Furnace Co. (Engelhard Minerals & Chemicals Corp.), Rockwood, Tenn.; Satralloy Inc., Steubenville, Ohio; Tenn-Tex Alloy Corp. of Houston, Houston, Tex.; and Union Carbide Corp., Alloy, W. Va., Marietta, Ohio, and Portland, Oreg. Fused salt electrolysis continued to be used by Chemetals Div., Diamond Shamrock Corp., Kingwood, W. Va., to make low-carbon ferromanganese sold under the trade name of Massive Manganese. The company was engaged in doubling capacity of this plant to 17,000 short tons per year. Satralloy Inc. began producing high-carbon ferromanganese at the beginning of October in one of six furnaces at Steubenville, Ohio. This plant was formerly owned and operated by Foote Mineral Co., primarily for production of chromium ferroalloys. U.S. shipments of ferromanganese from furnaces totaled 556,000 short tons compared with 574,000 tons in 1974 and 779,000 tons in 1973.

Table 5.—Ferromanganese and silicomanganese produced in the United States and manganese ore [1] consumed in their manufacture

Year	Production				Manganese ore [1] consumed (gross weight, short tons)			
	Ferromanganese			Silicomanganese (gross weight, short tons)	Foreign [2]	Domestic [2]	Per ton of ferromanganese made [3]	Per ton of ferromanganese and silicomanganese made [3] [4]
	Gross weight (short tons)	Manganese content						
		%	Short tons					
1971	759,896	78.6	597,205	165,000	1,820,408	7,033	2.4	1.9

Unidentified	17,549	51
Total	1,437,311	47

[1] Most, if not all, from U.S. Government surplus stockpile disposals.

The production reported in the various tables of this chapter is net production; that is, the quantity of ferromanganese produced for shipment outside the producing ferroalloy facility. It does not include the remelt material—fines, offgrade, or other ferromanganese output of the furnace—that was fed back to the furnace or lost in the plant, and which is included in gross data reported by the furnace operator. It does include ferromanganese made for use in the company's steel furnaces at the same or other locations.

Silicomanganese.—A large drop was recorded in production of silicomanganese in the United States to 143,000 short tons from 196,000 tons in 1974 and 184,000 tons in 1973. The silicomanganese figures represent net production produced for shipment. They do not include the silicomanganese that was produced for use as an intermediate for the production of medium- or low-carbon ferromanganese in the same plant. Silicomanganese shipments from furnaces were 126,000 tons in 1975, compared with 192,000 tons in 1974 and 196,000 tons in 1973. Six companies used eight plants to produce silicomanganese for shipment in 1975: Airco Alloys Div., Airco Inc., Theodore (Mobile), Ala.; Interlake Inc., Beverly, Ohio; Ohio Ferro-Alloys Corp., Philo, Ohio; Roane Electric Furnace Co. (Engelhard Minerals & Chemicals Corp.), Rockwood, Tenn.; Tenn-Tex Alloy Corp. of Houston, Houston, Tex.; and Union Carbide Corp., Alloy, W. Va., Marietta, Ohio, and Portland, Oreg. End-use consumption of silicomanganese—that is, consumption outside the ferroalloy plants—was 18.2% that of ferromanganese, compared with 15.9% in 1974 and 14.2% in 1973.

Spiegeleisen.—The New Jersey Zinc Co. continued to produce spiegeleisen in electric furnaces at Palmerton, Pa.

Pig Iron.—A total of 359,000 short tons of manganese-bearing ores containing over 5% manganese (natural) was consumed in the production of pig iron (or its equivalent hot metal). Domestic sources supplied 190,000 tons, of which 73,000 tons was manganiferous iron ore containing 5% to 10% manganese, 111,000 tons was ferruginous manganese ore containing 10% to 35% manganese, and 6,300 tons was manganese ore containing 35% or more manganese that was apparently obtained from GSA through its surplus stockpile disposal program. Foreign sources supplied 169,000 tons, of which 2,000 tons was manganiferous iron ore and 167,000 tons was manganese ore containing 35% or more manganese.

Battery and Miscellaneous Industries.—The ore reported in table 3 includes that consumed in making synthetic manganese dioxide by either electrolytic or chemical means, but it does not include consumption of the synthetic dioxide. Although some synthetic dioxide is used for chemical purposes, most of it is used in the manufacture of dry cell batteries, particularly for the manganese-alkaline type, premium or heavy-duty Leclanché (manganese dioxide-ammonium chloride-zinc) cells, and as a blend with natural ore in ordinary Leclanché cells.

The domestic ore and much of the foreign ore used for chemical and miscellaneous purposes did not meet national stockpile specification P-81-R for chemical-grade ore.

PRICES

Manganese Ore.—All manganese ore prices are negotiated, dependent in part on the characteristics and quantity of ore offered, delivery terms, and fluctuating ocean freight rates. Trade journal quotations reflect the paper's evaluation of the market. For 1975, contract prices for metallurgical manganese ore having a minimum manganese content of 47% to 48% manganese were $1.38 to $1.45 per long ton unit, c.i.f. U.S. ports. Although contracts for ore to be delivered the following year are normally negotiated in October or November, contracts for ore to be delivered in 1976 had not been made by yearend 1975.

Manganese Alloys.—The producer price for standard high-carbon ferromanganese, having a minimum manganese content of 78%, was maintained at $440 per long ton of alloy throughout the year. The price of imported alloy of the same grade, however, as quoted by Metals Week, dropped from $450–$460 at the beginning of the year, delivered at Pittsburgh and Chicago, to $440–$450 in March, to $410–$430 in May, and to $390–$415 for the last 2 months of the year.

Manganese Metal.—A dual price of 53/54 cents per pound prevailed throughout the year for standard or comparable grades of electrolytic manganese metal chips, f.o.b. producer plant, for shipments of 30,000 pounds or more.

FOREIGN TRADE

Exports of ferromanganese totaled 32,300 short tons valued at $10,601,354, compared with 7,011 tons valued at $2,203,957 in 1974. Of the 1975 total, Canada took 21,900 tons; West Germany, 3,360 tons; Sweden, 2,914 tons; the Netherlands, 1,381 tons; Romania, 1,084 tons; the United Kingdom, 460 tons; Turkey, 330 tons; Greece, 224 tons; Venezuela, 141 tons; Mexico, 107 tons; Brazil, 90 tons; the Republic of South Africa, 66 tons; Bolivia, 62 tons; Colombia, 58 tons; Ghana, 41 tons; France, 33 tons; Peru, 31 tons; Malaysia, 12 tons; and Italy, 6 tons. Exports classified as "manganese and manganese alloys, wrought or unwrought, and waste and scrap" totaled 3,256 tons valued at $3,318,222, compared with 2,318 tons valued at $2,118,803. This classification includes electrolytic manganese metal and manganese-copper alloys, but it does not include ferromanganese. Exports of ore and concentrate containing more than 10% manganese amounted to 204,523 tons valued at $13,886,100, compared with 223,088 tons valued at $13,656,462 in 1974. Of the total, large quantities having relatively low average values were distributed as follows: Spain, 80,000 tons; Mexico, 41,000 tons; Canada, 27,000 tons; Yugoslavia, 14,000 tons; and the Republic of Korea, 11,000 tons. These tonnages appear to have been largely, if not entirely, metallurgical ore obtained from GSA sales of Government surplus stocks.

The average grade of imported manganese ore in 1975 was 49% manganese, compared with 48% in 1974 and 1973. Brazil supplied 40% of this ore in 1975; Gabon, 31%; the Republic of South Africa, 13%; and Australia, 11%. Imports of manganiferous ore (more than 10% but less than 35% manganese) consisted of 185 short tons from Mexico having an average manganese content of 34%.

Ferromanganese imports for consumption continued at a high level, although down somewhat from those of the preceding year. France and the Republic of South Africa continued to be the principal suppliers. Both are countries in which a U.S. company has a substantial interest in a ferromanganese producer. Silicomanganese imports for consumption totaled 54,723 short tons containing 35,156 tons of manganese. Sources and tonnages (gross weight) were as follows: Japan, 19,909; Norway, 16,128; the Republic of South Africa, 8,524; Yugoslavia, 4,795; Spain, 2,425; Brazil, 2,203; the Republic of Korea, 243; Canada, 203; Mexico, 183; and France, 110. Imports for consumption classified as unwrought manganese metal, except alloys, and waste and scrap, totaled 4,378 short tons, compared with 2,506 tons in 1974. Of the 1975 total, 3,332 tons were from the Republic of South Africa, 785 tons from Japan, 142 tons from Canada, and 119 tons from the United Kingdom.

Imports for consumption classified as "manganese compounds, other" totaled 1,394 short tons, compared with 3,086 tons in 1974 and 4,355 tons in 1973. The sources, gross weights, and values per pound in 1975 were as follows: Japan, 1,114 tons (32 cents); the United Kingdom, 191 tons (6 cents); Belgium, 60 tons (32 cents); West Germany, 28 tons (87 cents); and France, less than 1 ton ($2.41). The imports from Japan and Belgium appear to have consisted largely, if not entirely, of synthetic manganese dioxide. Manganese sulfate imports consisted of only 2½ tons from Japan.

Tariffs.—The duty on manganese ore from most nations remained suspended, while the statutory rate continued to be 1 cent per pound of contained manganese and continued to apply to ore from the U.S.S.R. and the People's Republic of China.

Table 7.—U.S. imports[1] of manganese ore (35% or more Mn), by country

WORLD REVIEW

A comprehensive background report on sea-floor manganese nodules, the technology for their recovery, the mining interests, legislative concerns and international considerations involved, was prepared as a source of reference for congressional activity with respect to a national policy for deep sea-floor mining.[2]

A Manganese Centre was formed early in 1975 by producers and consumers, with headquarters in Paris, to promote the consumption of manganese and to foster cooperation in research and dissemination of information. Founding members were Aciéries de Paris et d'Outreau, Compagnie Minière de l'Ogooué, Compañía Minera Autlan, Elkem-Spigerverket A/S, N. V. SADACEM, Société Europenne des Derives du Manganes (SEDEMA), Société Minière de Kisenge, South African Manganese Ltd., and Ugine Aciers.[3]

Old trade routes for manganese ore were reestablished when the Suez Canal was reopened in June 1975 after having been closed for 8 years.

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the countries listed, Colombia, Cuba and the Territory of South-West Africa may have produced manganese ore and/or manganiferous ore, but available information is inadequate to make reliable estimates of output levels. Low grade ore not included in this table has been reported as follows in short tons: Czechoslovakia (about 17% Mn) 1973—1,100; 1974—1,072; 1975—1,101; Malaysia (apparently a manganiferous ferruginous ore; 28% to 30% Mn, 18% Fe in 1975; unspecified in 1973 and 1974) 1973—31,246; 1974—93,985; 1975—146,947; Romania (about 22% Mn) 1973—155,000; 1974—155,000; 1975—155,000; Republic of South Africa (15–30% Mn, in addition to material listed in table) 1973—73,333; 1974—98,769; 1975—123,131; Turkey (under 35% Mn) 1975 only—16,865.

[2] Estimated on basis of reported contained manganese.

[3] Exports.

[4] Figures are the sum of: 1) sales of direct shipping manganese ore, and 2) production of beneficiated ore, both as reported in the 1974 and 1975 editions of Anuario Mineral Brasileiro.

[5] Source: The National Economy of the U.S.S.R., Central Statistical Administration, Moscow. Grade represents the annual averages obtained from reported metal contents for the gross weights shown in the table.

[6] Of total 1973 output, 64% graded below 35% Mn, and 36% exceeded that grade. Comparable production breakdown for 1974 and 1975 not available, but 71% of 1974 total exports of 1,140,453 short tons were below 35% Mn.

[7] Iranian calendar year beginning March 21 of year stated.

Argentina.—Yacimientos Mineros Agua de Dionisio (YMAD), the state mining company, was reportedly developing the manganese-silver-gold deposits of Catamarca Province with expectations for production to begin in the second half of 1976.[4] These deposits have been under investigation since 1948.

Australia.—Manganese nodules containing iron, copper, nickel, uranium, and gold were found by the Royal Australian Navy at a depth of several hundred meters off Cape Leeuwin, Western Australia, over an area of 230,000 square miles.[5] ESB Inc.

[5] American Metal Market. News Briefs. V. 83, No. 28, Feb. 10, 1976, p. 2.

has joined with Century Storage Battery Co., Ltd., to form Ray-O-Vac Australia, Pty., Ltd., for the production and marketing of Ray-O-Vac dry cell batteries.

Brazil.—In addition to its premium pellets typically analyzing 58% manganese, Indústria e Comércio de Minerios, S.A. (ICOMI), offered the following grades of metallurgical manganese ore from the Serra do Navio (Amapá) deposits in 1975: 3- by ½-inch high-grade lump, typically analyzing 49% manganese, 5.5% iron, 2.5% silica, 5.5% alumina, 0.09% phosphorus, and 5.0% moisture; ½- by 5/16-inch screened ore containing 46% to 48% manganese for direct addition to blast furnace feed; and fines, typically analyzing 44% manganese and sized to 5/16 inch by 20 mesh, for sintering by the customer before addition to the blast or electric furnace. ICOMI is jointly owned by CAEMI S.A. (51%) and Bethlehem Steel Corp. (49%). The ores and pellets are shipped out of the port of Santana on the north bank of the Amazon River delta a few miles west of the small town of Macapa, Amapá Territory. The outloadings are typically on vessels of 15,000 to 25,000 tons, although vessels of 45,000 tons can be loaded. The pellet plant has enabled the utilization of previously unsold fines and low-grade ores.[6]

Late in 1975, ICOMI entered into an agreement with the Brazilian Government to limit exports of high-grade ore and pellets to 1.3 million tons per year, the average for exports over the last decade. With known reserves sufficient for only another 10 years at the present rate of production, and no large new Brazilian deposits of high-grade ore as yet proved, the Government has become concerned for future supplies of manganese for the country's growing steel industry. At the same time, a critical balance of payments deficit requires exports as an exchange earner. In this connection, it was reported that the Government would not approve export contracts for 1976 without a price increase. ICOMI, believed to be the only exporter in 1975, received slightly more than $50 per ton for its ore during the year. Because ocean freight rates dropped, the company hoped that it might achieve a higher price in 1976 without any cost increase to its customers.[7]

The Brazilian Government increased its prospecting efforts for manganese ore and was also conducting research looking toward utilization of the country's low-grade ores.[8] The National Mineral Production Department, Mines and Energy Ministry, announced the discovery of a large deposit of high-grade manganese ore near the Venezuelan border in the Uaupés district about 25 miles from the Rio Negro, a navigable tributary of the Amazon. The size of the deposit was estimated at 28 to 33 million tons of ore, and grades of 47% to 51% manganese were reported.[9]

In 1974, Brazil imported 13,000 tons of manganese ore and 367 tons of metal compared with 9,900 tons and 270 tons, respectively, in 1973.

Canada.—The two principal consumers of metallurgical manganese ore in 1974 were Chromasco Ltd. and Union Carbide Canada Ltd.,[10] both located at Beauharnois, Quebec. Ferromanganese production by Union Carbide was adversely affected by a strike that lasted from January 19 into July, although some production and shipments continued during the period.

Chile.—Manganese ore produced in 1975 had an average manganese content of 38.7%. Production of ferromanganese was 8,200 tons; silicomanganese, 3,000 tons.

Gabon.—Battery and chemical ore produced in 1975 totaled 44,000 tons.

Greece.—Concentrates produced in 1975 had a manganese content of 49% to 50%. Exports of pyrolusite in 1974 were 6,200 tons, of which 3,000 tons went to France, 2,800 tons to West Germany, and 400 tons to other countries. In 1975, at the gravity concentration plant at its Drama manganese mine, Financial Mining-Industrial & Shipping Corp. (FIMISCO) (Scalistiri Group) produced 8,300 tons and exported 7,700 tons of battery-grade manganese concentrate.

Indonesia.—More than 3,300 people were employed in the production of manganese ore in 1974. These labor-intensive, low-capitalization operations, with poor safety records, were by numerous small firms in Central Java and in the Jogjakarta area. Exports in 1974 totaled 17,600 tons. The distribution of this manganese dioxide ore, with the manganese dioxide content, was as follows: Japan, 10,000 tons (70% to 80%) plus 4,000 tons (60% to 70%); Taiwan, 2,600 tons (70% to 80%); and Europe, 1,000 tons (80% to 90%). Small quantities were consumed domestically for the manufacture of dry cell batteries. In 1975, demand was slack and miners were unable to sell their full production. Foreign investors were excluded from participation in manganese mining operations on Java, Madura, and Bali.

[10] Johnson, R. F. Manganese—1974. Mineral Development Sector, Department of Energy, Mines and Resources, Ottawa, Canada, July 1975, 8 pp.

Italy.—Production of high-carbon ferromanganese in 1974 was 77,400 tons, while that of refined grades of ferromanganese was 10,800 tons. The respective quantities for 1973 were 67,000 and 11,900 tons. Imports of manganese ore in 1974 totaled 340,000 short tons. Of this quantity, 169,000 tons came from Gabon and 130,000 tons were from the Republic of South Africa. The National Association of Italian Steel Industries estimated that 354,000 tons of manganese ore were consumed by the industry in 1974.

Japan.—Production of ferromanganese in 1975 was 717,000 tons; silicomanganese, 480,000 tons; electrolytic manganese metal, 9,111 tons; and synthetic manganese dioxide, 45,764 tons. The manganese ore produced in 1975 had an average manganese content of 26.9%, except for 72 tons of dioxide ore averaging 69.2% manganese dioxide.

Mexico.—Proven reserves of manganese ore at the Molango deposit of Cía. Minera Autlan, S.A. de C.V., were estimated to be 13,800,000 tons in 1975. Possible and probable reserves were estimated to be on the order of 220 million tons over an area of approximately 375 square miles.[11] The ore, consisting of manganese, calcium, magnesium, and iron carbonates, is of marine sedimentary origin. The company calcines and nodulizes it in a rotary kiln, using natural gas, to produce a nodule product, the manganese and iron of which is in the lowest state of oxidation (MnO and FeO). Analyses for crude ore and for nodules were presented as follows, in percent:

	Mn	Fe	SiO_2	CaO	MgO	P	H_2O
Carbonate ore	27.7	5.9	9.0	5.6	7.0	XX	XX
Oxide nodules	39.6	8.2	13.5	7.8	10.0	0.06	<1

XX Not applicable.

In 1975, the annual capacity of the calcining and nodulizing operation was being increased to 500,000 tons from 365,000 tons, with completion scheduled for late 1976. In January 1974, the manganese ferroalloy producer, Ferroaleaciones Teziutlán with two plants in the Teziutlán municipal district, State of Puebla, was merged into Cía. Minera Autlan to form a ferroalloy division. Installed capacity of the two plants, Aire Libre and Copper, was 41,000 kilovolt-amperes with four furnaces at each plant. During 1975, construction proceeded on the company's new ferromanganese plant at Tamós in the municipal district of Pánuco, State of Veracruz, 12 miles from the port of Tampico. Two closed furnaces of 33,000 kilovolt-amperes will produce 110,000 tons per year. The first furnace was expected to come onstream in the first quarter of 1976; the second furnace, in the third quarter.[12] Also in 1975 at the Molango deposit, the company began development leading to conversion of its Tetzintla open pit operation to an underground mine. Of the 365,000 tons of nodules produced in 1974, 71% were exported.

Peru.—The only manganese production in 1974 was from the Japanese-owned Minas de Gran Bretaña. The average manganese content was 31%.

Portugal.—Eurominas Electrometalurgica SARL, a subsidiary of Pechiney Ugine Kuhlmann, brought onstream a new ferromanganese plant reported to be capable of producing 110,000 tons per year. According to preliminary data, 22,500 tons of manganiferous iron ore were produced in Portugal in 1975, averaging 41.4% iron and 8.7% manganese.

South Africa, Republic of.—South African Manganese Ltd. and Amcor Ltd. merged on April 1, 1975, forming South African Manganese Amcor Ltd.[13] South African Manganese has been, and continues to be, the Republic's principal producer of manganese ore, its contribution being estimated at more than 50% of the country's total production in 1974. The company's production in 1974 and 1975 was from four mines in Cape Province: Wessels, reputedly the world's largest underground manganese mine; Hotazel, now nearly mined out; Mamatwan; and Lohathla. Associated Manganese Mines of South Africa Ltd. continued to be the country's second largest producer. Other important producers in 1974 were Consolidated African Mines Ltd.; Marble Lime & Associated Industries, Ltd. (Gopani mine); National Manganese Mines (Pty) Ltd.; Rio Rita Mines (Pty) Ltd.; Roodepan Manganese Corp. (Pty) Ltd.; and Rooi Riet Base Metals (Pty) Ltd. During 1975, United States Steel Corp. acquired a 19% interest in Associated Manganese Mines of South Africa as part of an agreement involving procurement of iron ore from Associated's large reserves.

[11] Galvan, L. Manganese Nodulizing Kiln Operation. Pres. at Am. Min. Cong. Conv., San Francisco, Calif., Sept. 28–Oct. 1, 1975, AMC Preprint, 11 pp.

[12] Work cited in footnote 11.

United States Steel's interest in Feralloys Ltd., a ferromanganese-producing subsidiary of Associated Manganese, was 44% according to United States Steel's 1975 Annual Report. The previously announced expansion program of Feralloys Ltd. was reported by Associated Manganese to be progressing satisfactorily with completion expected in the first half of 1977. Associated Manganese estimated that the capital requirements of its program for increasing manganese ore production in 1976 would be approximately $3,500,000.

Total production of the various grades of metallurgical ore in 1975 and 1974 was as follows, in short tons (1974 in parentheses): 30% to 40% manganese, 4,268,000 (3,336,000); 40% to 45%, 257,000 (291,000); 45% to 48%, 1,520,000 (240,000); and over 48%, 219,000 (1,254,000). Similarly, of the chemical ore produced: 35% to 65% manganese dioxide, 87,000 (103,000) tons; 65% to 75% manganese dioxide, 8,000 (6,000) tons. Production of ferruginous manganese ores containing 15% to 30% manganese and 20% to 35% iron was 123,000 tons and 99,000 tons, respectively. Local sales and exports of the various grades in 1974 were as follows (exports in parentheses): Metallurgical 30% to 40% manganese, 550,000 (3,007,000) tons; 40% to 45% manganese, 86,000 (206,000) tons; 45% to 48% manganese, 100,000 (254,000) tons; and over 48% manganese, 270,000 (1,055,000) tons; chemical 35% to 65% manganese dioxide, 104,000 (zero) tons; and 65% to 75% manganese dioxide, 8,000 (948) tons; and ferruginous, zero (129,000) tons. Production of ferromanganese in the 1974 fiscal year (October 1, 1973 to September 30 , 1974) was 355,000 tons, compared with 273,000 tons in fiscal 1973.

Thailand.—Production of battery-grade manganese ore (75% manganese dioxide) in 1975 was 4,000 tons, while exports totaled 1,000 tons. Chemical ore production (75% manganese dioxide and up) was 926 tons; exports, 220 tons. The metallurgical ore produced ranged in manganese content from 46% to 50%.

U.S.S.R.—The Soviet Union asked at least two United States producers of ferroalloys, also Western European companies, for bids on a ferromanganese plant of sufficient size to produce 1.1 million tons per year of high-carbon ferromanganese. The target date for completion was 1980.[14]

Upper Volta.—A 5-nation, 14-firm consortium was formed to develop the Tambao manganese deposit. The Government of Upper Volta and a group of 11 Japanese firms, including Mitsui & Co., Ltd., Japan Metals & Chemicals Co. Ltd., Nippon Kokan, K.K., Nippon Denko Co., Ltd. and Kobe Steel Ltd., appeared to be the prime movers in the venture at midyear. The other participants were Union Carbide Corp., the only U.S. interest; the West German firm, Exploration und Bergbau GmbH; and the French firm, Soc. du Manganese.[15] Reserves were estimated at 13 million metric tons of ore.[16] Earlier lower tonnage estimates, made subsequent to test drilling about 1967, had estimated the grade to range from 44% to more than 54% manganese. Construction of 220 miles of railroad to the present railhead at Ougadougou was expected to begin before yearend. Export will be from Abidjan, Ivory Coast, 700 miles by rail from Ougadougou.

Zaire.—Société Minière de Kisenge, formerly owned by the Belgian firm, Bécéka-Manganèse, was wholly owned by the Zairian Government in 1975. Of 188,000 tons of crushed ore produced in 1975, 7,000 tons were carbonate ore. Ore exports were 141,000 tons before the civil war in Angola closed the Benguela Railway by which ore was shipped through Angola to the port of Lobito. Economics will not permit shipment by any other route, and exports were not resumed although production and stockpiling at the mine continued.

ESB-Zaire S.P.R.L., in which ESB Inc., Philadelphia, Pa., has a 75% interest, completed construction of a dry cell manufacturing facility about the beginning of 1975.

TECHNOLOGY

Extensive tests on the use of low concentrations of the manganese organometallic, methylcyclopentadienyl manganese tricarbonyl (MMT), as an antiknock additive for unleaded gasoline were claimed by the producer, Ethyl Corp., to be economically attractive without significant adverse effects on car operation or exhaust emissions. At the maximum recommended concentration of 0.125 gram of contained manganese per gallon of gasoline, the octane rating could be raised approximately 2 points. This would provide a crude oil savings of about 1% compared with conventional processing methods used to achieve the same octane numbers. It was estimated that atmospheric manganese concentrations resulting from widespread use on freeways would be less than 1 microgram per cubic meter except under the most unfavorable weather conditions; median airborne concentration in urban areas would be 0.05 microgram per cubic meter. No catalyst plugging was observed under typical driving conditions; exhaust valve and spark plug life presented no problems at the recommended low concentrations.[17] Ethyl Corp.'s 1975 Annual Report stated that sales of MMT increased sharply and that 27 refiners were using it.

A study by the U.S. Environmental Protection Agency (EPA) of the possible environmental effects of the use of MMT in gasolines led to the conclusion that it would not present a "direct disbenefit" to public health, but that its effect on emissions other than manganese was not clear. Many of the EPA tests used concentrations of MMT greater than 0.125 gram per gallon of gasoline, the maximum recommended by Ethyl Corp.[18]

Experimental work by Mobil Research and Development Corp., Paulsboro, N.J., suggested that sea-floor manganese nodules from the Pacific Ocean would be a good absorbent for removing metals from petroleum residua and heavy oils. At relatively high temperatures (850° F), the metals deposit on the surface of the nodules and the demetallized oil can be processed conventionally to provide low-sulfur fuel oil, gasoline, or home-heating oil. It was suggested that an operation of this type could prove useful for processing the high-metal asphaltic heavy oils of California, Canada, and Venezuela.[19]

A study by Ledgemont Laboratory, Kennecott Copper Corp., Lexington, Mass., of various metallurgical processes for use on sea-floor manganese nodules suggested that one or more of the three following processes could be ready for commercialization after scale-up of equipment: Reduction and ammoniacal leaching, sulfuric acid leaching, and hydrochloric acid reduction and leaching. The ammoniacal leach process is similar to the Caron process that was used for Nicaro nickel laterite ores in Cuba; the high-pressure sulfuric acid leach process is based on the process that was used by Freeport Sulfur Co. on laterites at Moa Bay, Cuba; and the low-pressure hydrochloric acid leach process is the one that has been proposed by Deepsea Ventures, Inc. Only the low-pressure hydrochloric acid leach process requires recovery of manganese in addition to nickel, copper, and cobalt for its success, although a manganese "add-on option" is possible for the other processes. Nickel, copper, and cobalt do not occur as discrete minerals in the nodules, but are contained in the manganese oxides: Todorokite, birnessite, and delta MnO_2. A feature of the nodules is their extremely fine porosity of nearly 60% by volume. The comment was made that, because of intense competition, "proprietary process work must be well ahead of published information." Certain other processes, such as carbonyl chemistry, and the sulfur dioxide, nitric acid, and ferric chloride leaching processes, were not discussed primarily for lack of published material. An extensive bibliography and patent list was presented.[20]

[19] The Northern Miner (Toronto). V. 16, No. 27, Sept. 18, 1975, p. 7.

Since February 1973, by extensive recycling of steelmaking slags from its basic oxygen furnace and open hearth shops to its blast furnaces, Inland Steel Co. was able to recover a large quantity of manganese and greatly reduce its use of manganese-bearing ores. By providing a calcined lime, Inland Steel reduced the amount of raw flux required per ton of hot metal, and more hot metal was produced per ton of iron ore consumed. The principal disadvantages resulting from this practice were the buildup of phosphorus and chromium in the hot metal when large quantities (300 pounds of slag per short ton of hot metal) were used in the blast furnace burdens. Both of these elements adversely affect steelmaking operations and product quality, although steelmaking practices can be adjusted to handle the increased phosphorus. The average chemical analysis for these slags during the period August 21 to December 31, 1974, was as follows: Iron, 26.29%; manganese, 4.17%; phosphorus, 0.367%; sulfur, 0.160%; chromium, 0.27%; lime (CaO), 31.75%; magnesia (MgO), 7.47%; alumina (Al_2O_3), 2.30%; and silica (SiO_2), 13.13%.[21]

Several papers were presented at the 34th Ironmaking Conf., American Institute of Mining, Metallurgical, and Petroleum Engineers, Toronto, Canada, April 1975, on the use of processes other than manganese for control of sulfur in the iron-steelmaking cycle. Desulfurization of the hot metal by use of calcium carbide or various forms of magnesium was discussed.

Mercury

By Harold J. Drake[1]

Production of primary mercury totaled 7,366 flasks[2] valued at an estimated $912,227. Production was reported from 13 mines in California, Nevada, and New York. The threefold increase in output over that of the preceding year was accounted for principally by the opening of a new mine in Nevada.

Secondary production, including 500 flasks disposed of in January by the General Services Administration (GSA), declined 3% to 8,038 flasks.

Consumption declined 15% to 50,838 flasks. Declines by use ranged from 10% to 26% in major applications, with a 14% decline in use in electrical apparatus accounting for the largest loss in terms of volume. Usage in mildew-proofing paint was the only application reporting an increase. For most uses, the consumption declines prevalent in 1974 were reversed by the end of the second quarter of 1975 as consumption began to increase.

Consumer and dealer stocks rose 31% to 20,691 flasks, and producer stocks advanced 18% to 4,858 flasks.

Prices continued to decline, and by yearend, reached $117 per flask in New York and $77 per flask in London. The average U.S. price per flask for the year was $158.12 compared with $281.69 per flask in 1974.

Exports and reexports, at 494 flasks, were up only slightly from the 1974 level. Imports for consumption fell moderately to 43,865 flasks, a level 16% below that of the preceding year. Of the principal foreign suppliers, Canada, Mexico, and Spain recorded the greatest declines, but Italy recorded an eight-fold increase in shipments. The share of the U.S. market supplied by imports dropped to about 87% in 1975.

World production in 1975 totaled 251,226 flasks as reduced output was recorded in most countries. Some of the world's principal mercury producers formed an international association to promote the use of mercury and to attempt to stem the downtrend in prices. Countries originally represented included Spain, Italy, Yugoslavia, Turkey, Peru, and Algeria. Articles and provisions of the association were signed in April, and unsuccessful attemps were made thereafter to maintain a minimum flask price at various levels.

Legislation and Government Programs.—Government financial assistance on a participatory basis was available for mercury exploration projects through the Office of Minerals Exploration, U.S. Geological Survey, to the extent of 75% of the acceptable costs. No contracts were executed during 1975. GSA offered for sale 500 flasks of mercury monthly during 1975 but sold only the January offering.

The Federal Government concluded its hearings on the use of phenylmercury compounds in paints. During the hearings, the Environmental Protection Agency (EPA) attempted to prove that the phenylmercurics in paint were converted to environmentally hazardous methylmercury compounds, whereas paint manufacturers offered testimony that microorganisms demethylated methylmercury into inorganic mercury and methane gas thereby negating the harmful effects of methylmercury.

EPA proposed strict regulations to fine companies for discharging or spilling hazardous substances, such as mercury compounds, above specified levels. In the case of mercury compounds, the level was set at 1 pound or more. The maximum fine for each discharge or spill was set at

---

[1] Physical scientist, Division of Nonferrous Metals.

[2] Flask as used throughout this chapter refers to the 76-pound flask.

$500,000 but fines of more than $5,000 would be applied only if gross negligences were proven. Additional penalties would be applied for failures to notify EPA or local authorities of such discharges. The new regulations do not apply to companies having discharge permits issued by EPA or State authorities.

On March 14, EPA proposed National Interim Primary Drinking Water Regulations and held hearings, thereafter, on the proposed regulations. In addition, comments and information were received from representatives of State agencies, public interest groups, and others. The regulations proposed maximum contaminant levels in public drinking water and set the mercury level at 0.002 milligram per liter.

EPA published a study intended to determine the amount of mercury entering the environment and the manner in which it is redistributed, particularly with regard to its introduction into man's food chain.[3]

Congress has taken no action on authorizing the release of the 157,405 flasks of surplus mercury in the strategic stockpile. As of December 31, 1975, total strategic stockpile accumulations from all programs remained at 200,062 flasks.

r Revised.

DOMESTIC PRODUCTION

Production of primary mercury amounted to 7,366 flasks. Twelve mines recorded production in 1975, the same number as in 1974. Byproduct mercury continued to be produced at a gold mine in Nevada and a zinc smelter in New York. Mercury mine production was reported from California and Nevada only. Mines known to have produced mercury in 1975 included the Guadalupe, Manhattan-One Shot, the Oat Hill, the Knoxville, and the New Almaden in California and the Red Bird and McDermitt in Nevada.

On June 2, Placer Amex, Inc. formally opened its new McDermitt open pit mine near the site of the old Cordero mine in Humboldt County, Nev. The new mining facility has a designed production capacity of 20,000 flasks per year and a reserve of about 400,000 flasks in ore averaging about 10 pounds of mercury per ton. The plant has been carefully designed to comply with EPA's mercury emission standard of 5.1 pounds per day. Disposal of tailings in an environmentally acceptable manner is accomplished by impoundment behind impervious dams in ponds with impervious bottoms. The company is required to maintain monitoring wells to determine if any mercury escapes from the ponds.

The results of an examination of the Kolmakof mercury deposit in Southwestern Alaska were published.[4] Although the possibility of significant mineralization exists in the area, it was concluded that the Kolmakof deposit was small.

The average grade of all ore processed in 1975, including ore treated in concentrators, increased to 6.8 pounds of mercury per ton. Much of the increase was accounted for by the new McDermitt mine in Nevada.

Production of secondary mercury exclusive of GSA sales, totaled 7,538 flasks, a level 27% above that of 1974. Major sources of secondary mercury were industrial and control instruments, batteries, sludges, and dental amalgams.

1974	5,940	2,353	8,293
1975	7,538	500	8,038

CONSUMPTION AND USES

Consumption, reversing the upward trend of recent years, declined 15% to 50,838 flasks. Much of the decline was attributed to depressed economic conditions in the first half of the year. As economic conditions began to improve in the second half of the year, consumption of mercury also began to rise and by yearend, nearly every use reported increased demand.

Of the two largest applications, use in electrical apparatus declined 14% to 16,971 flasks and use in the preparation of chlorine and caustic soda declined 10% to 15,222 flasks. In the aggregate, these two uses accounted for 63% of total consumption. Use in industrial and control instruments declined 26% to 4,598 flasks, and use in dental preparations declined 23% to 2,340 flasks. Use as catalysts fell from 1,298 flasks in 1974 to 838 flasks in 1975. Similar losses occurred in agriculture use, down from 980 flasks to 600 flasks, and in pharmaceutical use, down from 597 flasks to 445 flasks. The only application reporting an increase over 1974 was mildew-proofing paint, which rose slightly to 6,928 flasks.

Of the 50,838 flasks consumed in 1975, 75% consisted of primary mercury, 21% of redistilled mercury, and 4% of secondary mercury. Primary mercury was used through the whole range of applications, whereas redistilled mercury was used principally in dental preparations, electrical apparatus, and industrial and control instruments, reflecting the high purity required in the three applications. The bulk of the secondary mercury was used in dental preparations, electrical apparatus, chlorine and caustic soda production, and industrial and control instruments.

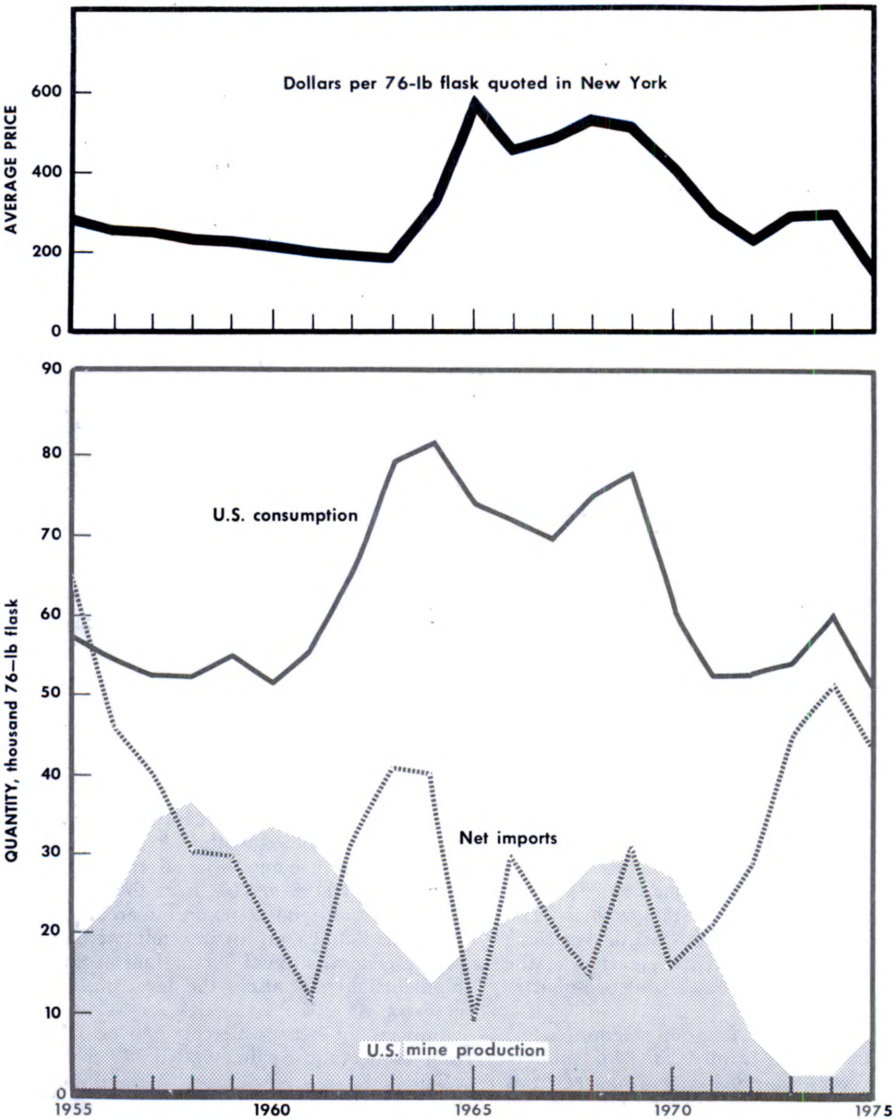

Figure 1.—Trends in production, consumption, and price of mercury.

PRICES

Prices of primary mercury dropped steadily during 1975, and by yearend were nearly half those of the beginning of the year. On December 29, 1975, the New York price of mercury was $123 per flask contrasted to $225 per flask on January 2, 1975. The average flask price for the year amounted to $158.12 compared with $281.69 in 1974. The London price suffered similarly, falling from $165 per flask on January 6, 1975, to $77 per flask at yearend. National and international price declines were attributed to decline in demand, world oversupply, the opening in the United States of the large McDermitt mine, and the possibility of mercury disposal from stockpiles held by the U.S. Government.

Table 8.—Average monthly price of mercury at New York and London
(Per flask)

Month	1974		1975	
	New York[1]	London[2]	New York[1]	London[2]

[2] Metal Bulletin, London; reported in terms of U.S. dollars.

FOREIGN TRADE

Exports of mercury totaled 339 flasks valued at $152,000 compared with 466 flasks valued at $270,000 in 1974. Reexports totaled 155 flasks valued at $68,000. Shipments to Canada, Colombia, Venezuela, Brazil, Saudi Arabia, and Taiwan accounted for 80% of the exports. The remainder went mainly to South American and African nations. Three-quarters of the reexports went to Canada and one-quarter to Taiwan.

Imports for consumption declined 16% to 43,865 flasks valued at $7.6 million. The average unit value for the year was $173.24 per flask compared with $267.31 per flask in 1974.

Imports from nations in the Western Hemisphere, Canada, Mexico, Peru, and the Philippines, in the aggregate, fell 44% to 16,129 flasks valued at $2.5 million. The low U.S. price combined with the opening of the McDermitt mine served to reduce imports from Canada by 24%, and to eliminate imports from the Philippines.

Imports from other principal suppliers, Spain, Italy, Algeria, Turkey, and Yugoslavia, in the aggregate gained 15% to 25,605 flasks valued at $4.8 million. A more than eight-fold increase in imports from Italy combined with a 2% increase in imports from Yugoslavia offset declines ranging from 11% to 84% from the others. Other nations tend to export mercury to the United States on an intermittent basis and, in general, annual fluctuations in their shipments do not affect the level of U.S. imports.

Imports of scrap mercury, principally from France and Spain, totaled 779 flasks.

The U.S. rate of duty on mercury imports during 1975 was $9.50 per flask.

Table 9.—U.S. exports and reexports of mercury

In 1974, 52,102 flasks ($13,858,283), Italy 705 flasks ($178,675), Yugoslavia 4,307 flasks ($1,174,480). In 1975, 44,472 flasks ($7,223,497), Italy 7,525 flasks ($1,151,729) the U.S.S.R. 600 flasks ($122,538), Yugoslavia 4,498 flasks ($645,967), and the People's Republic of China 350 flasks ($64,885).

WORLD REVIEW

World production of mercury declined to 251,226 flasks in 1975. Throughout most of the year, declining demand coupled with falling prices tended to keep mine output at or below levels of the preceding year. Large inventories throughout the world served to keep prices down when demand began to improve toward yearend.

• Estimate. p Preliminary. r Revised.
[1] Exports.

Japan.—Nomura Kosan Co. Ltd. continued to be the only Japanese supplier of mercury as all mercury mines remained closed in 1975. The company reclaims a large volume of mercury from used electrical appliances. Chlorine and caustic soda producers continued large capital outlays to convert production facilities from mercury cells to diaphragm cells. Conversion was expected to be completed in 1978.

Spain.—Recent exploration at the Almaden mine has reportedly located much larger reserves than previously indicated. Exploratory drilling at the site of an ancient abandoned mercury mine north of the Almaden discovered an extremely rich deposit of cinnabar at a comparative shallow depth. The extent of this new deposit had not been ascertained at yearend.

U.S.S.R.—Development of rich new deposits discovered in recent years has made the U.S.S.R. self-sufficient in mercury and permitted exportation of the metal. Exports by the U.S.S.R. in 1975 are believed to have been greater than 25,000 flasks.

TECHNOLOGY

Mercury ore was roasted using a fluidized-bed technique that allowed maximum extraction from particles with a wide range of sizes.[5] Good fuel economy was realized. Mercury ore was leached with aqueous sodium hypochlorite to produce mercury chloride, which in turn was stripped from the aqueous solution using a mixture of trioctylamine and kerosine, followed by a highly alkaline aqueous solution.[6]

Scanning electron microscopy was used to study mercury ore from the Almaden mine in Spain in an attempt to determine the origin of the ore deposit.[7] The study indicated that mineralization of the main ore body occurred with molten cinnabar and mineralization on the edge of the deposit occurred via a vapor-phase impregnation.

Determination of mercury using a spectrophotometer with 6-phenyl-2,3-dihydro-*as*-triazine-3-thione was reported.[8] A number of investigations on various kinds of mercury were conducted to develop analytical techniques useful in environmental pollution studies.[9]

Mercury was used successfully as a probe for capacitance-voltage measurements of certain types of silicon and other semiconductors.[10] The determination of mercury by the cold vapor atomic absorption method was investigated to ascertain the reason for the sometimes unreliability of the method.[11]

A multistage air sampler for mercury was developed that successfully detected mercury down to 0.3 nanogram with a precision of ±5%.[12] Stringent wastewater standards have led to the use of a variety of techniques for the removal of mercury from wastewater.[13]

Cold vapor atomic absorption used with two methods of decomposition was investigated for reliability in determining mercury in petroleum and petroleum products.[14] Both methods were successful, but considerable experience with the decomposition method was necessary to achieve reliable results. The cold vapor atomic absorption technique for determination of mercury was improved.[15]

Vicinal diothiol chemical components (VDT) were incorporated in alkaline cellulose to produce a very effective mercury adsorbent.[16] In one example, VDT cellulose reduced a mercury concentration of 1 part per million to less than 5 parts per billion.

Mica

By Stanley K. Haines [1]

Domestic production of mica [2] consisted of a small quantity of sheet mica from North Carolina and a large quantity of scrap and flake mica. Production of scrap and flake mica decreased 2%, and output of ground mica decreased 3%.

Consumption of block and film mica, predominantly imported material, decreased significantly in both quantity and value in 1975. Mica splittings (muscovite and phlogopite) also suffered a large decline in consumption in 1975. Exports of all classes of mica decreased in quantity but increased in value. Imports of uncut sheet and punch and scrap increased in quantity, while manufactured mica declined in quantity and value.

Legislation and Government Programs.—The Defense Materials Inventory stockpile objectives for all categories of sheet mica remained the same. Shipments of excess mica by the General Services Administration (GSA) amounted to 3,445,000 pounds.

---

[1] Physical scientist, Division of Nonmetallic Minerals.

[2] Unless stipulated in the text, mica refers to the muscovite mica variety.

DOMESTIC PRODUCTION

Sheet Mica.—A small quantity of sheet mica was produced and sold locally in North Carolina. The sheet mica was generally of low quality and grade, and was not mined as the primary product of the producing company.

Scrap and Flake Mica.—Production of scrap and flake mica declined 2% from that of 1974 to 134,885 short tons in 1975. The value declined 5% from $5,474,636 in 1974 to $5,219,461 in 1975. North Carolina remained the leading mica-producing State, with 56% of total production. The remaining 44% of scrap and flake output came from Alabama, Arizona, Connecticut, Georgia, New Mexico, Pennsylvania, South Carolina, and South Dakota. Scrap and flake mica was produced from the beneficiation of pegmatite ores, clay deposits, and weathered pegmatite and schist areas.

Leading producers of scrap and flake mica were Harris Mining Co., Spruce Pine, N.C.; Western Mica Co., Div. of United States Gypsum Co., Chicago, Ill.; Mineral Industrial Commodities of America, Inc., Santa Fe, N.M.; Feldspar Corp., Spruce Pine, N.C.; and Kings Mountain Mica Co., Inc., Kings Mountain, N.C.

r Revised.

[1] Includes finely divided mica recovered from mica and sericite schist, and mica that is a byproduct of feldspar and kaolin beneficiation.

[2] Includes Alabama, Connecticut, Georgia, New Mexico, Pennsylvania, and South Dakota.

Ground Mica.—Sales of ground mica decreased 3% in quantity and 8% in value. Dry-ground mica production increased slightly in both quantity and value, while wet-ground mica decreased 29% in quantity and 26% in value. Sixteen companies, operating a total of eighteen plants, processed scrap and flake mica. Fourteen of these plants produced dry-ground mica, three produced wet-ground mica, and one produced wet- and dry-ground mica.

Leading producers of ground mica were Harris Mining Co., Spruce Pine, N.C.; United States Gypsum Co., Chicago, Ill.; Deneen Mica Co., Inc., Micaville, N.C.; Mineral Industrial Commodities of America, Inc., Santa Fe, N.M.; and Thompson-Weinman & Co., Cartersville, Ga.

[1] Domestic and some imported scrap.
[2] Data do not add to totals shown because of independent rounding.

CONSUMPTION AND USES

Sheet Mica.—Consumption of block and film mica suffered a large drop in 1975. Fabrication of block and film mica (muscovite and phlogopite) declined 36% to 622,848 pounds. Of the total consumption, 94% was muscovite block, 5% was phlogopite block (magnesium mica), and 1% was muscovite film.

Vacuum tubes required 64% of the total muscovite block fabricated. The remaining fabricated block was used in gage glass and diaphragms (2%) and capacitors and other uses (34%). Lower than Stained muscovite block mica was in greatest demand and accounted for 58% of consumption; Stained accounted for 40%; and Good Stained or better, 2%.

Muscovite film consumption continued to decline, dropping from 8,671 pounds in 1974 to 7,243 pounds. The film was consumed primarily in the fabrication of capacitors.

Muscovite block and film was consumed by 13 companies in 7 States. North Carolina, New Jeresy, and New York had three consuming plants each, while Massachusetts, Ohio, Pennsylvania, and Virginia had one plant each.

Phlogopite block consumption dropped from 62,513 pounds in 1974 to 28,512 pounds. Phlogopite was consumed by six companies in five States. Virginia and New Jersey were the primary fabricating States.

In 1975, Victory Mica Manufacturing Co. and Ford Radio and Mica Corp. ceased sheet-mica-fabricating operations and sold their stocks of mica. Other companies in the industry may be adversely affected by the closing of the RCA electronic tube plant in New Jersey.

Consumption of mica splittings (musovite and phlogopite) decreased from 6,186,000 pounds in 1974 to 4,746,000 pounds. India and the Malagasy Republic supplied the bulk of the splittings consumed domestically. Splittings were fabricated into various built-up mica products by 10 companies with 11 plants in 8 States. Five plants located in Ohio, New York, and New Hampshire consumed 3.9 million pounds of splittings, or 82% of total consumption.

The declines in sheet-mica consumption were due to a combination of problems. First was the general economic recession, which decreased demand for consumer appliances that use a good deal of the mica fabricated in the United States. Second was the continual increase in prices for the raw material. As mica becomes more and more expensive, consumers are finding cheaper substitutes, both mica based (mica paper) and nonmica based (ceramics).

Built-up Mica.—This mica-based substitute was produced in various forms, primarily for use as electrical insulating material. Production of all major built-up mica products declined in quantity and value. The forms of built-up mica in greatest demand were segment plate 32%, molding plate 26%, and tape 19%.

Reconstituted Mica.—Five companies manufactured this mica-based material from good-quality delaminated scrap mica. The manufacturing companies were General Electric Co., Schenectady, N.Y.; U.S. Samica Corp., Rutland, Vt.; Acim Paper Corp., Hempstead, N.Y.; Essex Group, United Technologies Corp., New Market, N.H.; and Corona Films Inc., West Townsend, Mass.

Essex Magnet Wire & Insulation Div. in New Market, N.H., opened its new

30,000-square-foot building; the company has developed new manufacturing and control methods to produce mica paper. The products include a 100% mica product, which is further processed by adding various binders, heat, and pressure to produce the desired mica-paper insulating products. The Essex facility is the only integrated processing plant in the United States whereby the raw mica is converted from scrap into high-quality finished products in one continuous process. Current capacity of the facility is in excess of 1 million pounds per year.

The newly formed Vermont corporation, U.S. Samica Corp., purchased the operating equipment for mica-paper production from 3M Co. and will continue to produce and market mica paper. The firm has developed a new mica paper called Micanite II, which is between actual built-up mica from splittings and traditional mica paper. The product is a heavy paper usable for a variety of electrical insulating applications.

Ground Mica.—The ground-mica industry suffered a 3% drop in sales below the already depressed level of 1974. Sales of ground mica for use in roofing materials, paint, and joint cement declined 13%, 34%, and 36%, respectively. Use of ground mica in wallpaper increased over 1974 levels.

STOCKS

At yearend there was 4.1 million pounds of sheet mica in fabricators' stocks. Of this total, 85.2% was splittings, 14.6% was block, and 0.2% was film. This information was obtained by a direct canvass of sheet-mica fabricators.

PRICES

The average values per pound of muscovite sheet in 1975, based on consumption data, follow: Block, $2.59; film, $3.90; and splittings, $0.55. The average value per pound of phlogopite sheet mica, also based on consumption data, follow: Phlogopite block, $2.14; and phlogopite splittings, $0.87.

The average value of scrap and flake mica produced during 1975 was $38.78 per ton, slightly lower than the 1974 value. Prices for wet- and dry-ground mica quoted in the Chemical Marketing Reporter essentially remained at 1974 levels.

Table 10.—Price of dry- or wet-ground mica in the United States in 1975[1]

	Cents per pound
Dry-ground:	
Joint cement, 100 mesh	4–5
Plastic, 100 mesh	4–5
Roofing, 20 to 80 mesh	2-½–3-½
Wet-ground:[2]	
Paint or lacquer, 325 mesh	11–13
Rubber	11–13
Wall paper	12–18

[1] In bags at works, carlots, unless otherwise noted.

[2] Freight allowed east of the Mississippi River.

Source: Chemical Marketing Reporter. V. 208, No. 25, Dec. 22, 1975.

FOREIGN TRADE

Total mica exports decreased 32% in quantity but increased 9% in value. Over 55% of the sheet, scrap, flake, and ground mica exported was shipped to Canada, the United Kingdom, Venezuela, Saudi Arabia, and France. Reported export data did not provide information on the grade or type of mica exported, but it is assumed that the major portion of the material exported was ground mica.

Imports of waste and scrap mica increased 61% in quantity. Sheet mica imports increased 14% in quantity, but decreased 27% in value. Processed-mica imports decreased 23% in quantity and 40% in value.

WORLD REVIEW

World production of all forms of mica increased less than 1% from 1974 to 1975. India was the world leader for production of sheet mica. Brazil, the Malagasy Republic, and Argentina were other major sheet-mica-producing countries. The United States continued as the major world producer of scrap and flake mica for grinding purposes.

Canada.—Construction began on a new processing plant to beneficiate the Suzorite phlogopite mica from a huge deposit in northeast Quebec. The decision to move ahead with a full-scale plant was the result of successful operation of a pilot plant for the past 2 years. First-year capacity of the new plant is expected to be 10,000 tons per year, with planned expansion to 30,000 tons per year in 3 years. The project is a joint venture of Le Sociëté Mineralurgique Laviolette of Montreal and Marietta Resources International, Ltd., a subsidiary of Martin Marietta Corp.

India.—Production of mica in India was primarily from about 100 regularly operated mines, with some production coming from smaller intermittent producers. The Government of India proposed and recommended implementing a program whereby a foreign company ordering mica would be required to purchase 40% of the order from the Government's Mica Trading Co. (MITCO), and the remaining 60% from traditional suppliers.

Floor prices for sheet mica were increased for most categories. In December, there were floor-price revisions for some categories of mica that resulted in a lower floor-price increase than had been set earlier in the year. In particular, one-half-inch scrap was originally set to increase 100% in price, but the Government later lowered the increase to 75% over the floor prices in effect before July 1975.

Export Linkers, one of India's leading exporters of mica scrap has expanded its activities into the production of ground mica. The grinding plant will have a capacity of 3,000 tons per year, and will allow the company to supply mica in sizes ranging from 9.5 millimeters down to 20 micrometers.[3]

From April 1974 to February 1975, the U.S.S.R. imported over 36% of the total Indian sheet-mica exports. Czechoslovakia, Romania, Hungary, East Germany, Poland, and West Germany increased their imports of sheet mica from India.[4]

U.S.S.R.—The U.S.S.R. is planning an underground mine followed by a strip mine to work the Kovdorsk phlogopite deposits. The first stage of production involves an underground room-and-pillar mine. The rooms will then be caved. Following this, a strip mining operation will remove the vermiculite overburden and work down to the phlogopite rubble.[5]

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, the People's Republic of China, Romania, Southern Rhodesia, Territory of South-West Africa, and Sweden are known to produce mica, but available information is inadequate to make reliable estimates of output levels.

[2] Exports.

[3] Revised to zero.

[4] Includes micanite and other built-up mica.

[5] Includes condenser film, washer, disks.

[6] Includes sheet, strips, powder.

[7] Less than ½ unit.

TECHNOLOGY

A combination of Suzorite phlogopite mica and glass polyester was used for various general applications. Tests were performed whereby the form and content of the mica and glass were varied to find the optimal combination with acceptable performance. The Suzorite and glass composites were shown to have a higher modulus, equal or slightly lower strength, and lower cost per unit weight than equivalent glass laminates.[6]

In addition to various sprayed-up techniques the Martin-Marietta laboratory has developed methods for compounding and injection-molding low-cost, high-strength thermoplastics that incorporate Suzorite phlogopite as a reinforcing agent. Applications currently being tested include several automobile components where strength and performance requirements are high.

Mykroy Ceramics Div. of Synthane-Taylor Corp. has developed a lower cost glass-bonded mica. The natural-mica-filled material is used for electrical and electronic applications that require tolerance of high heat. The product, Mykroy 740, can withstand continuous operating temperatures of 399° C. The ceramic is machinable with standard tooling.[7]

Mica has been used in cosmetics for many years. An example of a recent use is in the Almay Color Rich Dry Shadow by Almay, Inc. The mica imparts a pearly, sparkling, look when applied. The mica is pure or coated with titanium dioxide. In this particular case, the mica is used as a nonallergenic ingredient.

Molybdenum

By John T. Kummer [1]

Production of molybdenum, both domestic and worldwide, declined in 1975. The decline was primarily due to lower byproduct recovery at copper mines. The year was also marked by lower consumption of molybdenum, especially by the iron and steel industry, which accounts for about 80% of the consumption each year. Despite reduced demand, prices of concentrate and other molybdenum products increased during 1975. Reportedly, higher operating expenses and the expansion of mining and production facilities necessitated the price increases. As a result of the expansion of mining and production capacity, domestic supply should be sufficient to meet demand for molybdenum in the near future.

Legislation and Government Programs.—In recent years, the General Services Administration (GSA) has been authorized to dispose of all molybdenum materials in the national stockpile because domestic production capacity was considered adequate to supply national emergency needs. By the close of 1975, all materials had been sold. Sales in 1975 consisted of 1,798,125 pounds of molybdenum in molybdenum disulfide (MoS_2) and 291,048 pounds in ferromolybdenum. GSA reported an inventory of sold, but unshipped, materials containing 1,133,680 pounds of molybdenum in MoS_2, 280,082 pounds in ferromolybdenum, and 72,696 pounds in molybdic oxide at yearend 1975.

[r] Revised.

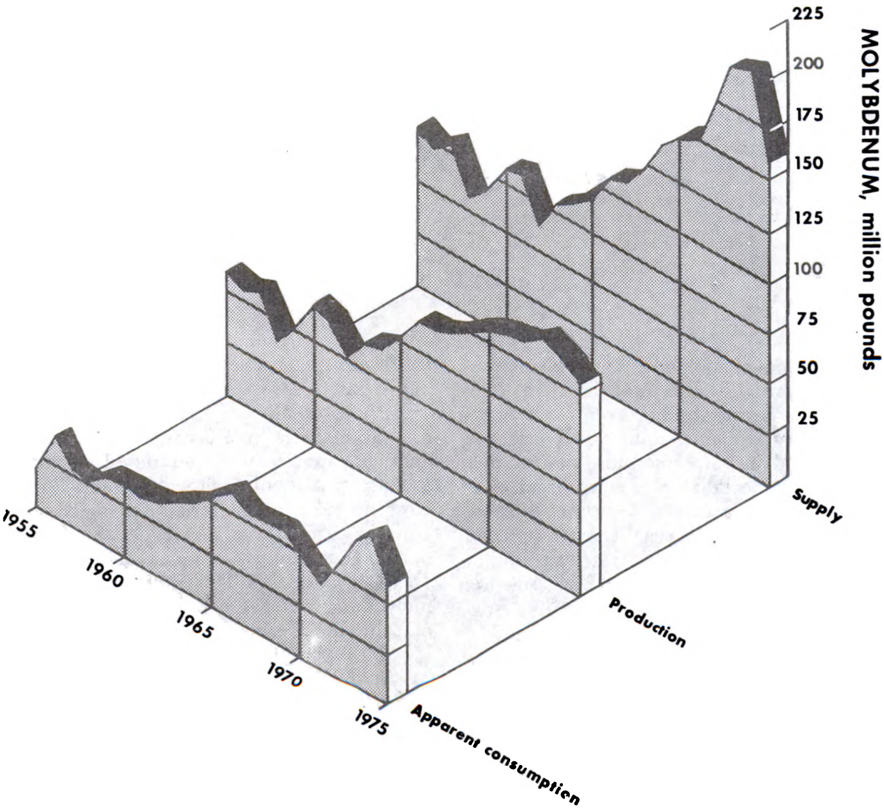

Figure 1.—Apparent consumption, production, and supply of molybdenum in the United States.

DOMESTIC PRODUCTION

Production of molybdenum in the United States decreased by 6 million pounds, 5.4% lower than in 1974 and 8.5% below the record production year of 1973. The declining production of molybdenum has been caused by lower output from byproduct plants at copper mining operations and, to a lesser extent, by the closure in late 1974 of the Urad mine (AMAX Inc.), a source of primary ore since 1967. A reduction in demand, associated with the general slowdown of industrial activity during 1975, also contributed to the drop in molybdenum production.

The two sources of primary molybdenite ore, the Climax mine of AMAX Inc., and the Questa mine of Molycorp, Inc., produced 70.7 million pounds of molybdenum, about 67% of the domestic output in 1975. Compared with that of 1974, production from primary ore deposits decreased 4.9%, chiefly due to the shutdown of operations at the Urad mine. The Climax mine was again the world's leading producer, supplying 33% of the estimated world production.

Production of byproduct molybdenum amounted to 35.3 million pounds, or 33%

of domestic output in 1975. Recovery of molybdenum as a byproduct declined 6.4% compared with that of 1974. A 2.2-million pound decrease in molybdenum output from 13 copper ore deposits accounted for most of the decline. The small amount of molybdenum obtained from tungsten and uranium operations also decreased in 1975. The two largest producers of byproduct molybdenum were the Sierrita mine of Duval Sierrita Corp. in Arizona and the Utah mine of Kennecott Copper Corp. Other significant sources of byproduct molybdenum were the Esperanza and Mineral Park properties of Duval Corp., the San Manuel mine of Magma Copper Co., and the Cyprus Pima property of Cyprus Mines Corp. All four are copper porphyry ore deposits located in Arizona.

Expansion of mining and processing facilities was continued during 1975 to insure future availability of molybdenum ore and primary products. Noteworthy among these activities has been the development of the Henderson mine and mill near Empire, Colo., by AMAX Inc. Mine and mill buildings had been erected and ore processing equipment was being installed by the end of 1975. The third, and final, mine shaft was completed in 1975. "Hole through" of the 9.6-mile-long ore haulage tunnel was accomplished in July 1975. The tunnel can accommodate a double tracked, fully automated railway system that will transport ore from the underground mine to the ore processing plant 14.4 miles away. Haulage capacity of 42,000 tons per day of molybdenite ore will be provided by 6 unit trains, each with 4 locomotives and 30 22-ton ore cars. Initial production, scheduled for the second half of 1976, was set at 2,000 tons per day with a goal of 30,000 tons per day by 1980.

AMAX Inc., has invested approximately $400 million since 1967 in developing the Henderson mine complex. Care has been taken to minimize environmental impact of land-clearing operations, road and building construction, and tailings disposal. The mill will use water recycled from the tailings pond to reduce contamination of the natural drainage system. By 1980, it is projected that output of the mine will reach 50 million pounds of molybdenum per year, an amount which will nearly double AMAX's current production.

In 1975 the molybdenum chemical plant at Fort Madison, Iowa, which has been under construction by AMAX Inc., since 1973, started converting technical-grade molybdic oxide to ammonium molybdates and high-purity molybdic oxide. A roaster complex and sulfuric acid plant was scheduled for completion in late 1976. During 1975, AMAX also expanded and modernized its production facility at Langeloth, Pa. Production capacity for molybdic oxide and lubrication-grade molybdenum disulfide was increased, and a sulfuric acid plant was under construction. With the addition of the Fort Madison plant, AMAX will have the capability to process in excess of 100 million pounds of molybdenum yearly by 1980.

Exploratory drilling during 1974 and the first half of 1975 by Molycorp revealed additional mineralization within its Questa mine holdings in northern New Mexico. Three separate mineralized zones have been encountered and, to finance further exploratory work, Molycorp entered into a partnership with Kennecott Copper Co. in July 1975. The agreement calls for Kennecott to contribute a minimum of $5 million prior to July 1977 for drilling and evaluation of the findings. Should this exploration add sufficient reserves to support a 20-million-pound annual mining and milling operation, the two companies would jointly develop the deposit. Production at the new mine would be shared by the two partners with both contributing equally to production and operating costs. It was hoped that the mining feasibility of these prospects could be determined by the end of 1976. The existing Questa mine was temporarily excluded from the partnership.

The Pinto Valley copper mining complex, developed by Cities Service Co., began continuous operation during 1975. Byproduct molybdenum will be recovered from the copper porphyry deposit located near Miami, Ariz. At design capacity, the concentrator should produce about 4.8 tons per day of molybdenum concentrate averaging 85% MoS_2. This production rate translates to an annual output of 1.5 to 2 million pounds of molybdenum from the Pinto Valley operation.

Cyprus Bagdad Copper Co., a subsidiary of Cyprus Mines Corp., progressed with expansion work at its Bagdad open pit copper mine in Arizona. Site preparation for the primary crusher and concentrator was completed in 1975. The concentrator will have the capacity to treat 40,000 tons per day of copper-molybdenum ore, a tonnage which should substantially increase the output of byproduct molybdenum from the mine. All major construction was on schedule, and the entire expansion project was expected to be completed late in 1977. Cyprus Bagdad sold over 400,000 pounds of molybdenum in 1975.

Cyprus Mines Corp. also continued to study the potential of its Thompson Creek molybdenum prospect in central Idaho. During 1975, consultants were retained to make capital and operating cost estimates, to study open pit and underground mining methods for the deposit, and to make metallurgical bench-scale and pilot plant tests. Cyprus has spent 8 years on its investigation of the prospect; a decision as to mining feasibility could be made in 1976.

Duval Corp. commenced operation of a newly constructed ferromolybdenum plant adjacent to its Esperanza property near Tucson, Ariz. The facility cost $2 million and will have the capacity to produce 3.5 million pounds of ferromolybdenum per year. Silicothermic reduction of molybdic oxide, supplemented with powdered aluminum, is used to produce the ferromolybdenum.

The Pesses Co. initiated construction of a ferroalloy plant near Pulaski, Pa., in 1975. Completion was scheduled at the end of the first quarter of 1976. In addition to supplying its own requirements, the company planned to produce ferromolybdenum and other ferroalloys on a toll basis. The company is a manufacturer of products for the metalworking and ceramic industries.

Table 2.—Production, shipments, and stocks of molybdenum products in the United States in 1975

(Thousand pounds contained molybdenum)

	Molybdic oxides [1]	Metal powder	Ammonium molybdate	Sodium molybdate	Other [2]	Total
Received from other producers	8,194	9	837	41	20	9,101

Shipments	71,747	3,147	2,074	1,054	11,767	89,789
Producer stocks, Dec. 31	17,130	473	1,347	170	3,743	22,863

[1] Includes technical and purified molybdic oxide and briquets.

[2] Includes ferromolybdenum, calcium molybdate, phosphomolybdic acid, molybdenum disulfide, molybdic acid, pellets, molybdenum pentachloride, and molybdenum hexacarbonyl.

CONSUMPTION AND USES

Domestic consumption of molybdenum in concentrate form decreased 1.7 million pounds, 2% less than in 1974. Most of the concentrate, except that purified to lubrication-grade molybdenum disulfide and a small amount added directly to iron and steel furnaces, was roasted to technical-grade molybdic oxide. Molybdic oxide was consumed directly or converted to other molybdenum products.

End-use consumption of molybdenum materials decreased 18.5% compared with that of 1974 (table 3). Nearly all categories of end-use consumption experienced a decline due to the economic situation that prevailed during 1975. Especially significant was the drop in iron and steel production, since that industry utilizes most of the molybdenum consumed each year. Molybdenum consumed during 1975 in the production of full alloy, stainless, tool, and high-strength low-alloy steels declined 7%, 37%, 55%, and 11%, respectively, compared with that of 1974. Total consumption in all steels, cast irons, and superalloys equaled 43,952,000 pounds of molybdenum 17.8% below the 1974 level of consumption. Consumption of molybdenum to manufacture mill products decreased 32% and for chemical and ceramic uses, 24%.

The decrease in molybdenum consumption during 1975 was viewed as temporary by molybdenum industry officials. The marketing of new steels containing molybdenum as an alloying element was expected to augment molybdenum consumption. Among such newly developed products were a group of ferritic stainless steels, which contain 1 to 4% molybdenum. These steels exhibit marked corrosion resistance and were developed for use in hot-water tanks, heat exchangers, water tubing, and for other equipment exposed to severe chemical environments. Increased consumption of molybdenum was expected in high-strength low-alloy steels for large-diameter pipelines and for steel pipe used in drilling oil and gas wells.

Research was directed toward the development of nonmetallurgical uses for molybdenum. Molybdenum is utilized in catalysts for petroleum refining and was expected to find similar use in coal liquefaction and gasification processes. New applications were investigated for purified molybdenum disulfide as a lubricant and as an additive to oil and greases to reduce wear.

Table 3.—Consumption of molybdenum materials, by end use in 1975
(Thousand pounds contained molybdenum)

End use	Molybdic oxides	Ferro-molybdenum [1]	Ammonium and sodium molybdate	Other molybdenum materials [2]	Total

W Withheld to avoid disclosing individual company confidential data; included in "Miscellaneous and unspecified."

[1] Includes calcium molybdate.

[2] Includes purified molybdenum disulfide, molybdenite concentrate added directly to steel, molybdenum metal powder, molybdenum metal pellets, and other molybdenum materials.

[3] Includes magnetic and nonferrous alloys.

STOCKS

At the close of 1975, industry stocks of molybdenum totaled 40.3 million pounds, 14% less than at yearend 1974. Molybdenum in stocks at mines and plants decreased 43%, those at producer plants increased 42%, but those at consumer plants decreased 44% compared with 1974 figures.

PRICES

Published prices for molybdenum concentrate and other molybdenum products increased twice during 1975, once at the beginning of the year and again at the end of September. The price of Climax concentrate increased 14% and averaged $2.48 per pound of contained molybdenum during the year. Reportedly, higher operating costs and expenditures for expansion of mining and production facilities accounted for the increase in molybdenum prices. Yearend prices as published in Metals Week for molybdenum products per pound of contained molybdenum follow:

Climax concentrate	$2.62
Byproduct concentrate	$2.20–2.55
Climax oxide/cans	2.90
Dealer oxide	2.90–2.95
K–1 oxide/cans	2.90
K–2 oxide/cans	2.83
Ferromolybdenum/Climax lump	3.44
Ferromolybdenum/Climax powder	3.50
Ferromolybdenum/dealer export	3.45–3.50

FOREIGN TRADE

Exports.—Exports of molybdenum in concentrate and oxide totaled 62.6 million pounds in 1975, 20% less than in 1974. This quantity represented about 59% of U.S. production for the year. The Netherlands, Belgium-Luxembourg, Japan, and West Germany received 84% of the exports of molybdenum in concentrate and oxide forms. Compared with the export level in 1974, the decrease in exports in 1975 was due to decreased demand associated with the economic recession that affected most industrialized nations in 1975. Despite the decrease in quantity exported, the total value of molybdenum concentrate and oxide exports increased about 6% to $159.6 million in 1975.

Exports of ferromolybdenum totaled 2,241,000 pounds, 45% less than in 1974. Canada and Japan received 46% of the ferromolybdenum exported. The total value of ferromolybdenum exported was $4.8 million, down from $7.1 million in 1974.

Other molybdenum materials exported in 1975 included metals and alloys in crude form and scrap, wire, powder, and semifabricated forms. The gross weight of these materials was 959,000 pounds compared with 974,000 pounds in 1974; total value was $5.8 million compared with nearly $6.9 million in 1974.

Imports.—In general, a relatively small quantity of molybdenum enters the United States each year as imported material. Molybdenum imports during 1975 included concentrate, ferromolybdenum, metal products, waste and scrap, and chemicals. The total value of these materials rose to $7.7 million compared with $2.6 million in 1974.

The large increase in value of imported molybdenum materials is attributable to significantly greater imports of concentrate in 1975. The molybdenum contained in imports of concentrate totaled 2,566,680 pounds compared with 155,124 pounds in 1974. The value of concentrate imports during 1975 was about $5.9 million or approximately $2.30 per pound of contained molybdenum. Concentrate was imported from Canada, Chile, Peru, and the Philippines. Canada supplied 74% of the concentrate.

A small quantity of ferromolybdenum containing 3,493 pounds of molybdenum and valued at $10,266 was imported from the United Kingdom and Canada. Imports of 43,084 pounds (gross weight) of wrought and unwrought metal valued at $448,079 came from eight countries. Austria supplied 71% of the metal. Material in which the chief value is molybdenum was imported from the Netherlands and Japan. This material contained 71,983 pounds of molybdenum, valued at $463,112. The gross weight of waste and scrap imported from four countries was 44,672 pounds, valued at $101,073.

Molybdenum chemicals and related products that entered the United States during 1975 included ammonium molybdate containing 50,324 pounds of molybdenum and valued at $154,834; molybdenum compounds containing 73,260 pounds of molybdenum and valued at $198,832; mixtures containing 6,019 pounds of molybdenum and valued at $73,084; and 469,050 pounds (gross weight) of molybdenum orange valued at $317,774. Canada, Chile, and the Netherlands were the chief suppliers of molybdenum chemicals in 1975.

[2] Duty on waste and scrap temporarily suspended.

WORLD REVIEW

World molybdenum production decreased about 10.4 million pounds compared with that of 1974. The decline was primarily due to lower byproduct recovery of molybdenum at copper operations. Molybdenum production of 155.3 million pounds by market economy countries was principally from the United States (68%), Canada (18%), and Chile(13%).

Canada.—Estimated production of molybdenum declined 3,322,000 pounds in 1975, 11% lower than in 1974. About half of the Canadian output was byproduct molybdenum produced at copper mining operations. The weak worldwide market for copper in 1975 resulted in a decrease in copper output and a corresponding decrease in molybdenum production. Nevertheless, Canada continued to be the second leading world producer of molybdenum.

Exploratory and developmental work on molybdenum properties continued at several sites in the western provinces of Canada. Vestor Explorations, Ltd., carried on exploratory drilling at its Carmi molybdenum prospect south of Kelowna, British Columbia. It was reported that the property may contain a potential 100 million tons of molybdenite ore. Further exploration to outline mineralized zones was scheduled for 1976.

Dynamic Mining Exploration, Ltd., expanded its Thelon-Dazan project holdings in the Baker Lake area of the Northwest Territories. Substantial uranium and molybdenum mineralization has been discovered, and additional drilling was planned to determine the value of the prospect.

Brynnor Mines Ltd., a subsidiary of Noranda Mines Limited conducted a feasibility study on open pit mining of its Boss Mountain property, which is currently mined by underground methods. The low-grade molybdenum reserves amenable to open pit recovery were estimated at over 40 million tons. The mine reportedly contained sufficient high-grade ore reserves to permit mining operations at the present level until the latter part of 1977.

Kitla Exploration, Ltd., was investigating a molybdenum-uranium prospect on a 1,200-acre lease near Black Lake, Saskatchewan. Trenches were excavated to expose the mineralized zone, which reportedly is workable by open pit mining methods.

Climax Molybdenum Co. of British Columbia, Ltd., a subsidiary of AMAX Inc., U.S.A., extended its lease on the Ruby Creek prospect near Atlin, British Columbia. The property has been leased by Climax from Adanac Mining and Exploration, Ltd., since 1973, and about $500,000 has been spent on drilling and other investigative work.

Climax also purchased the Roundy Creek prospect in the Alice Arms area from United Chieftain Resources, Ltd. The property reportedly was obtained for about $300,000 and a royalty on future production at a rate of 5 cents per pound of contained molybdenum. At the nearby Kitsault, British Columbia, property, Climax also was considering a resumption of molybdenum mining. The mine and associated concentrator, formerly owned by Kennecott Copper Corp., has been inoperative since 1972.

Chile.—Compañía Minera Andina, a State-owned Chilean company, announced plans to build a molybdenite plant with an annual output capacity of about 770,000 tons. Financing for the construction will come from a $14 million loan from Japan's Sumitomo Metal Mining Corp., Ltd. No date for construction or expected operation was scheduled.

Greenland.—Nordisk Mineselskab A/S reportedly sought an extension of a lease from the Government of Denmark on a molybdenum prospect near Mastersvig, Greenland. Reevaluation of drilling data and other information indicated that further exploration on the property was warranted.

Mexico.—Mexxon Mines Ltd. continued exploration of its El Palmor copper-molybdenum-tungsten deposit in northern Mexico. During 1974, the company completed exploratory drilling of two large structural anomalies on the property and low-grade mineralization was encountered. Extensive geochemical surveys were underway during 1975 to locate additional target areas.

New Zealand.—A drilling program was started by New Zealand Cities Service Ltd. to explore the Taipo molybdenum prospect. The property is located northeast of Nelson on the South Island.

Peru.—Mina Aquila S.A., a newly organized private corporation, secured a $3 million loan to develop a copper-molybdenum deposit near Chimbote, in the province of Sihaus. The funds, obtained from the Export Development Corp., will be used principally to purchase engineering services and mine and concentrator equipment from various Canadian concerns.

[1] In addition to the countries listed, Argentina, North Korea, Nigeria, Romania, South-West Africa, and Spain also produce molybdenum, but information is inadequate to make reliable estimates of output levels.

[2] Less than ½ unit.

TECHNOLOGY

Bureau of Mines researchers developed a method for separating and extracting molybdenum and rhenium from an aqueous solution derived by electrooxidation of sulfide minerals.[2] Previous experiments had shown that the extraction of 98% to 99% of the molybdenum and rhenium from low-grade molybdenite concentrates by an electrooxidation process was technically feasible. In the current investigation, molybdenum and rhenium were extracted from an electrooxidation process solution with a tertiary amine solvent. Results indicated that essentially all of the molybdenum and rhenium was extracted by the solvent and that greater than 90% of the molybdenum could be recovered from the column effluent. The final $(NH_4)ReO_4$ product contained less than 80 parts per million impurities.

Cyprus Mines Corp. developed a process for separating talc from molybdenite more efficiently.[3] The slurry, which remains after copper values have been extracted, is treated with a water-soluble salt of a weak base and strong acid (such as aluminum sulfate), then with a water-soluble salt of a weak acid (such as sodium silicate). Talc or other hydrophobic magnesium silicates are depressed while molybdenite is removed by froth flotation. The process has been used since 1971 at the copper mining facilities operated by Cyprus Pima Mining Co. and has replaced conventional roasting and talc flotation techniques.

---

[2] Fischer, D. D., D. J. Bauer, and R. E. Lindstrom. Recovery and Separation of Molybdenum and Rhenium From a Process Solution. BuMines RI 8088, 1975, 12 pp.

The Metallurgical Research Dept. of The Anaconda Company developed a system using lignin sulfonate to separate molybdenite from clays and talc.[4] In the system, a primary circuit initially separates copper minerals from molybdenite and other floatable constituents of the bulk ore. The molybdenum concentrate is then treated with milk-of-lime (CaO) and large quantities of lignin sulfonate, which selectively depresses molybdenite. Tests indicated that recovery of molybdenum exceeded 95% at about pH 11.9; the upgraded concentrate contained about 45% molybdenum. The process performs best on silicates and clay; recovery and grade of molybdenum decline as the proportion of carbonates and sulfates in the original concentrate increased. Anamax Mining Co., a partnership of The Anaconda Company and AMAX Inc., tested and utilized the process at its Twin Buttes copper operations in Arizona.

The properties of molybdenum disulfide and its behavior as a dry lubricant and as a constituent in suspensions and greases were reviewed.[5] Lubricating effects of MoS_2 as a bonded film and as a matrix material in plastics and metals were also discussed. Additions of a small amount of graphite or antimony trioxide was found to enhance the performance of MoS_2 in many lubrication applications. A mechanism of oxide interaction has been proposed to explain the improved quality of these mixed solid lubricants.[6]

For a number of years, investigations have been conducted on evaluating the effect of MoS_2 additions to engine oil on automotive performance. A review of these studies and recent experimental results were published.[7] Statistical analysis of fuel consumption data indicated an average improvement in fuel consumption of 4.4% due to a 1% weight addition of MoS_2 to engine oil. The MoS_2 additions appeared to decrease engine wear and sludge accumulation, while not adversely affecting emission levels.

The beneficial effects of MoS_2 on the mechanical properties of thermoplastics was reviewed.[8] The properties of polymer-MoS_2 composites were discussed with respect to crystallinity of polymers, bonding interaction between MoS_2 and polymers, and polymer properties as affected by the size, shape, and surface of MoS_2 particles.

The potential of molybdenum compounds as flame retardants and smoke suppressants was examined.[9] Laboratory tests showed that additions of molybdenum trioxide to a plasticized polyvinyl chloride (PVC) significantly decreased the flammability and smoke generation of a burning sample. Similar improvements were obtained on polyester samples treated with molybdenum trioxide and ammonium molybdates. The best results were achieved when molybdenum compounds were used in combination with antimony trioxide or aluminum trihydrate.

Patent activity during 1975 was concerned with methods of upgrading and refining molybdenite ores. Patents were granted for the recovery of molybdenum from roasted molybdenite concentrate by acid leaching;[10] for the separation of molybdenite from other sulfides in flotation concentrates by roasting with silica sand;[11] for the recovery of molybdenum from copper reverberatory furnace slag;[12] for a new roasting apparatus to recover high-purity molybdenum trioxide from concentrate;[13] for a process that selectively removes oxidized metal impurities by alkaline leaching of molybdenite concentrate;[14] for the separation of molybdenite from copper sulfide ore concentrate using lignin sulfonate to depress molybdenite;[15] for the froth flotation separation of molybdenite from gangue, which includes talc or other hydrophobic magnesium sillicates;[16] and for the recovery of molybdenite or other sulfide values from ores containing clays or talc by froth flotation.[17]

Natural Gas

By Gordon W. Koelling [1] and Leonard L. Fanelli [2]

Marketed production of natural gas in the United States declined approximately 1.5 trillion cubic feet (Tcf) to 20.1 Tcf in 1975. This 6.9% decrease, the second consecutive annual decrease and only the second decrease since 1938, followed the rapid depletion of the Nation's proved natural gas reserves during recent years.

Total consumption of natural gas (including extraction losses) in 1975 was 20.4 Tcf, 7.7% less than in 1974. The industrial sector, the largest user of natural gas, experienced the greatest decline, 1.3 Tcf, and the electric utilities sector registered a decrease of almost 0.3 Tcf. Declining consumption in those sectors during 1975 was related to a 39.1% increase in the net curtailments of firm delivery commitments by pipeline companies and to a general decline in the Nation's economic activity. Residential use of natural gas increased 138 billion cubic feet (Bcf); growth in the commercial sector was insignificant.

Table 1.—Salient statistics of natural gas in the United States

	1971	1972	1973	1974	1975
Supply:					
Marketed production [1] million cubic feet	22,493,012	22,531,698	22,647,549	21,600,522	20,108,661
Withdrawn from storage do	1,507,630	1,757,218	1,532,820	1,700,546	1,759,565
Imports do	934,548	1,019,496	1,032,901	959,284	953,008
Total do	24,935,190	25,308,412	25,213,270	24,260,352	22,821,234
Disposition:					
Consumption do	22,676,581	23,009,445	22,965,914	22,110,623	20,409,875
Exports do	80,212	78,013	77,169	76,789	72,675
Stored do	1,839,398	1,892,952	1,974,324	1,784,209	2,103,619
Unaccounted for do	338,999	328,002	195,863	288,731	235,065
Total do	24,935,190	25,308,412	25,213,270	24,260,352	22,821,234
Value at wellhead:					
Total thousand dollars	4,085,482	4,180,462	4,894,072	6,573,402	8,945,062
Average cents per thousand cubic feet	18.2	18.6	21.6	30.4	44.5

[1] Marketed production of natural gas represents gross withdrawals less gas used for repressuring and quantities vented and flared.

NOTE.—Domestic production as used in the Bureau publication "Minerals and Materials/monthly survey" represents marketed production less the shrinkage (extraction loss) resulting from the extraction of natural gas liquids.

Proved reserves of natural gas declined 3.8% from 237.1 Tcf at yearend 1974 to 228.2 Tcf by yearend 1975 as annual discoveries failed to equal production for the seventh time in the last 8 years. Extensions to known fields during 1975 totaled 6 Tcf, and new reservoir discoveries in old fields and new field discoveries accounted for 4.1 Tcf. Revisions of previous reserve estimates and changes in underground storage resulted in a net addition of 0.7 Tcf.

The average wellhead value of natural

---

[2] Survey statistician, Division of Fuels Data.

gas increased 46.4% to 44.5 cents per thousand cubic feet (Mcf) in 1975. During the same year, the average retail price for gas delivered to consumers rose 33.4% to 119.3 cents per Mcf.

Exports of 73 Bcf in 1975 were 5.4% less than in 1974. About 72.9% of total 1975 exports was shipped from Alaska to Japan as liquefied natural gas (LGN). The remaining exports, which were transported by pipeline, were almost equally divided between Canada and Mexico.

Natural gas imports declined slightly to 953 Bcf in 1975. Almost all of this gas was shipped from Canada via pipeline. LNG shipments from Algeria totaled only about 5 Bcf and, for the first time since 1955, no imports were received from Mexico.

Efforts to supplement natural gas supplies through the gasification of liquid fuels continued. Eleven such plants were operational, two were under construction, and two were planned as of yearend 1975.

Six pilot projects for the development and testing of processes for the production of high-Btu gas from coal were operational or under construction at yearend 1975. An additional three projects involving the production of low-Btu gas from coal were also operational or under construction. The Bureau of Mines continued its experimental coalbed degasification project during the year. Several gasification projects involving biomass conversion were also under development.

Research programs involving fracturing techniques to stimulate flow from economically submarginal gas reservoirs, including these in the Upper Devonian shales of the Eastern United States, were in progress. The U.S. Geological Survey initiated studies of the methane saturated Gulf Coast salt water aquifers penetrated by a number of onshore wells.

The Federal Power Commission (FPC), which regulates the sale, transportation, and price of gas moved in interstate commerce, continued to apply a single uniform national base rate for interstate natural gas sales by producers. As of late 1975, the single uniform national base rate had escalated to 52 cents per Mcf. This rate applied to gas from wells commenced since January 1, 1973, and to new dedications of gas to interstate commerce since that date.

Leasing of Federal lands for the exploration and development of natural gas (and crude oil) resources continued under the authority of various public land acts. In 1975, the Federal Government leased 1.7 million acres on the Gulf of Mexico Outer Continental Shelf and off southern California for bonus bids totaling approximately $1 billion. An additional 1.3 million acres off the southern California coast were offered for lease sale in December 1975.

Notice of a proposed regulation to establish emergency procedures for granting priorities and allocating natural gas under the Defense Production Act of 1950, to assure adequate gas supplies for vital defense activities, was issued by the Department of the Interior during 1975. This regulation would be applicable only in exceptional cases where, in the event of actual or imminent shortages, FPC and the appropriate State regulatory commission lack jurisdiction to direct delivery of natural gas to meet defense needs.

The Office of Pipeline Safety (OPS), responsible for safety regulation of natural gas pipelines, reported that the total number of pipeline failures declined 7% during 1975, and that the number of fatalities resulting from these failures decreased from 24 to 14. Damage by outside forces was the cause of 71.4% of total failures (table 2).

Federal gas pipeline safety standards, contained in Part 192 of Title 49 of the Code of Federal Regulations, were amended to provide for the transportation of double-jointed pipe by railroad, to update welding and weld inspection requirements, to improve specifications for plastic pipe, to prescribe new marketing requirements for gas pipelines, and to establish requirements for odorization of gas in transmission lines. Notices of proposed rulemakings were issued with respect to emergency plans, cast iron pipelines, offshore pipeline, pipe-bending limitations, and the updating of documents incorporated by reference in Part 192.

DOMESTIC PRODUCTION

Gross withdrawals of natural gas (table 3), including marketed production, gas returned to the formation for pressure maintenance, and that vented or flared; totaled 21.1 Tcf in 1975, approximately 7.6% less than in 1974. Marketed production declined 6.9% to 20.1 Tcf during 1975, and the quantity of gas used for repressuring decreased 20.3% to about 0.9 Tcf. Quantities vented and flared dropped 20.9% to 0.1 Tcf.

Gross withdrawals from gas wells declined 6.9% in 1975 to 17.4 Tcf, and gas withdrawals from oil wells dropped 10.9% to 3.7 Tcf. Increased gross withdrawals were registered by only 7 of the 31 producing States and the quantities involved were small. The largest gain, 23.3 Bcf, was in Alaska.

The combined decrease in gross withdrawals registered by the two largest producing States, Texas and Louisiana, was equivalent to approximately 89% of the country's total net decline in 1975. Texas showed a decline of 9.8%, almost two-thirds of which was accounted for by a drop in production from gas wells; Louisiana registered a decrease of 8.6%, most of which also was due to a decline in gas well production.

Almost three-fourths of the total marketed natural gas production was from Texas and Louisiana. Marketed production data for leading producing States are shown in the following tabulation:

State	Marketed production in 1975 (Bcf)	Change from 1974 (percent)	Percent of total U.S. marketed production in 1975
Texas	7,486	−8.4	37.2
Louisiana	7,091	−8.6	35.3
Oklahoma	1,605	−2.0	8.0
New Mexico	1,217	−2.2	6.1
Kansas	844	−4.9	4.2
California	318	−12.9	1.6
Wyoming	316	−3.2	1.6
Others	1,232	+1.5	6.0
Total	20,109	−6.9	100.0

Gas well completions (table 4) in 1975 totaled 7,580, a net increase of 341, or 4.7%, over that of 1974. The largest increase in gas well completions, 292, occurred in Texas where continuing development of the Laredo field and exploratory and development drilling in the Ozana-Sonora area in the southwest part of the State were partially responsible for increased activity. Other significant increases in completions were in Pennsylvania (172) and Montana (134), where most wells are relatively small producers. In Ohio, where a large number of shallow wells were drilled during recent years, the number of gas well completions fell sharply from 1,050 in 1974 to 555 in 1975.

Completions of exploratory wells (table 5) in 1975 decreased 1.9% to 1,171. Texas accounted for 48.8% of these completions.

Data on gas well completions include condensate wells. The latter are wells that produce from high-pressure natural gas reservoirs, some of which contain considerable quantities of liquid hydrocarbons in the pentanes and heavier range described generically as "condensate."

The number of gas and condensate wells producing at yearend 1975 totaled 130,364 (table 6). This was an increase of 3.2% over the 1974 yearend total and 11% more than the number of wells producing at yearend 1970.

CONSUMPTION AND USES

Consumption (wet) of natural gas in 1975 totaled 20.4 Tcf, a 7.7% decrease from 1974 (table 7). Gas delivered to consumers declined 8% to 17.6 Tcf during 1975 when it accounted for 86% of total consumption (table 8). Of the remainder, 6.8% was used as lease and plant fuel, 2.9% was used for pipeline fuel, and 4.3% was accounted for by extraction losses (shrinkage) at gas-processing plants.

Residential use increased 2.9% to 4,924 Bcf in 1975 when it accounted for 28% of total deliveries to consumers. Most of the rise in residential use occurred in the contiguous Pacific, Mountain, and West South Central census regions.

The increase in the total number of residential consumers during 1975 was insignificant. Data on the number of residential customers by Census Regions for the years 1965, 1974, and 1975 are as follows:

Census regions	Residential consumers (thousands)		
	1965	1974	1975
New England	1,504	1,623	1,626
Middle Atlantic	7,381	7,779	7,594
East North Central	8,011	9,439	9,493
West North Central	3,005	3,519	3,587
South Atlantic	2,926	3,569	3,597
East South Central	1,684	2,001	1,967
West South Central	4,017	4,811	4,698
Mountain	1,523	2,151	2,227
Pacific	5,251	6,617	6,727
Total	35,302	41,509	41,516

The use of gas by the commercial sector increased slightly to 2,268 Bcf in 1975 despite a 1.2% decline in the number of customers. This sector accounted for 12.9% of total deliveries to consumers.

The industrial sector remained the largest user of natural gas, accounting for 39.7% of 1975 deliveries to consumers. However, total consumption by this sector dropped 16% to 6,979 Bcf during the year. Relatively low economic activity and curtailments of deliveries by many interstate pipelines contributed to this abrupt decline. Most of the gas used by industry was consumed as fuel. Petroleum refineries, which used 946 Bcf, and primary metal industries, which used an estimated 850 Bcf, were the principal fuel-consuming industrial sectors. Other important industrial users of gas for fuel included the nonmetallic, paper, and food products sectors. The principal nonfuel use of gas involved the chemicals industry, which used it as a feedstock, primarily in the production of fertilizers and plastics. In 1975, an estimated 1,300 Bcf was used by the chemicals industry both as feedstock and for fuel.

Use of natural gas in the electric utilities industry continued to decline in 1975 when consumption by this sector dropped 8.2% to 3,147 Bcf. The decrease was greatest in the West North Central region where consumption declined 100 Bcf, but decreases were registered in all regions except the West South Central where an increase of 201 Bcf occurred.

The decline in natural gas supply during 1975 forced many gas-distributing companies to deny service to new customers and to curtail supplies to some existing users (tables 10–12). FPC reported that net curtailments of firm delivery commitments of the major interstate pipeline companies for the year April 1975 through March 1976 totaled 2,801 Bcf, a deficiency of 19.7%. Net interruptible curtailments for the same period were reported at 330 Bcf, a deficiency of 54.8%. Firm curtailments for the year ending March 1976 were 39.1% higher than those for the preceding period and interruptible curtailments rose 40.6%.

The milage of field and gathering, transmission, and distribution pipelines in service at the end of 1975 was up only 0.6% from that of the previous year. Most of this increase was due to an increase in the milage of gas distribution mains, which reflected the continuing expansion of the gas utility industry into less densely populated areas. Data on the nations natural gas pipeline network are as follows, in miles:

	1963	1973 [r]	1974 [r]	1975
Field and gathering	60.7	65.9	66.4	68.5
Transmission	200.9	263.1	262.2	262.6
Distribution	448.3	638.8	645.6	648.9
Total	709.9	962.8	974.2	980.0

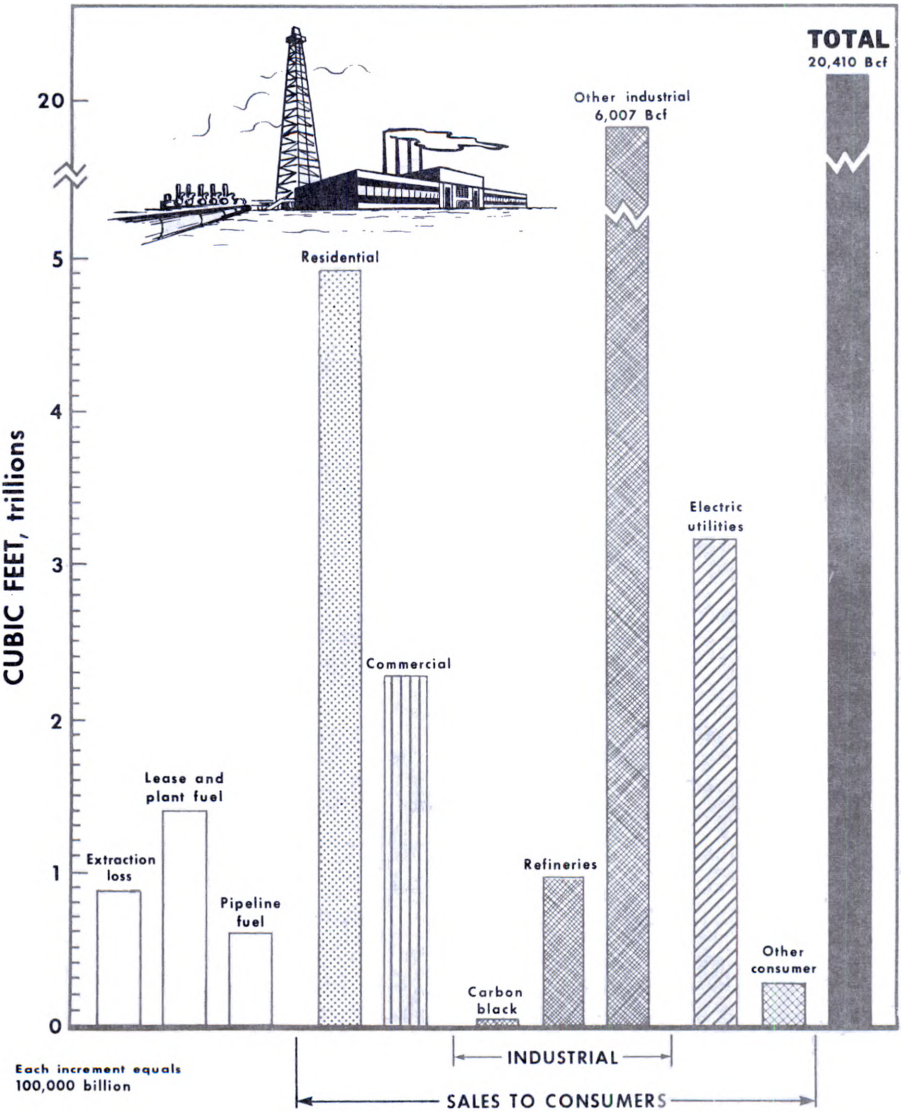

Figure 1.—Disposition of natural gas consumed in the United States by principal use.

RESERVES

Discoveries of natural gas failed to equal production during 7 of the last 8 years, and proved reserves declined 22% during the period. In 1975, the quantity of gas discovered was considerably less than that produced, and proved reserves dropped 3.8% from 237.1 Tcf at yearend 1974 to 228.2 Tcf by yearend 1975, according to the Committee on Natural Gas Reserves of the American Gas Association (AGA).

Additions to proved reserves reported for the United States in 1975 aggregated nearly 10.8 Tcf, approximately 21% more than in 1974 (table 15). Almost 57% of net additions to reserves in 1975 were offshore in the Gulf of Mexico. The largest addition to reserves, 6 Tcf, involved extensions to known fields. Approximately 53% of these new reserves were in Louisiana and Texas. Almost 50% of the 2.4-Tcf total for new field discoveries were in Louisiana (including offshore). New reservoir discoveries in old fields totaled approximately 1.7 Tcf, over 73% of which was in Texas and Louisiana. Net revisions of previous reserve estimates and net changes in underground storage accounted for the remaining 0.7 Tcf of reserve additions.

There were some net increases during 1974 in the reserves of natural gas in 18 States. However, significant increases occurred in only three States, Kansas with almost 1 Tcf (accounted for almost entirely by revisions), and Alabama and California with approximately 0.3 Tcf each. Reserves in Texas dropped 7.5 Tcf, or 9.6%; those in Louisiana declined 2.7 Tcf, or 4.3%.

Natural gas reserves committed to interstate pipelines declined during 1975 for the eighth consecutive year. Dedicated domestic reserves dropped 10.1% in 1975, and domestic gas produced and purchased by interstate pipelines declined 6.9% from the 1974 total of 13.0 Tcf to 12.1 Tcf in 1975. The reserve-production ratio for interstate reserves dropped from 9.3 at yearend 1974 to 9.0 by yearend 1975. Additional data are shown in the following tabulations:

Figure 2.—Trends in annual additions to natural gas reserves.

STORAGE

The development of additional underground storage capacity for natural gas continued during 1975. Total reservoir capacity increased 4.4% from 6,364 Bcf in 1974 to 6,644 Bcf by yearend 1975. The number of underground storage facilities increased from 367 in 1974 to 376 in 1975. These storage facilities were located in 26 States.

Most storage reservoirs are depleted fields. Of the 376 storage reservoirs in use, 319 or nearly 85% were of this type. Most of these reservoirs are located in the northeastern United States, primarily in the oldest oil- and gas-producing provinces. In Pennsylvania, where oil production dates back to 1859, depleted fields converted to storage facilities totaled 68 at yearend 1975. West Virginia had 38 reservoirs of this type as of the same date. The second largest concentration of storage reservoirs was in the Midwest, primarily in Michigan where 37 were in use.

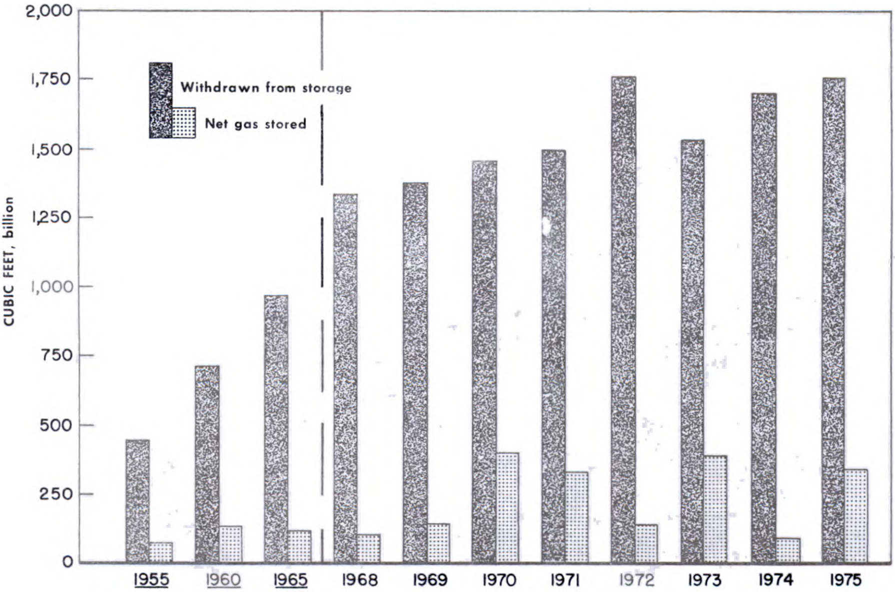

Figure 3.—Trends in net gas stored underground in U.S. storage fields.

Where depleted oil or gas fields are not available, other types of underground storage reservoirs have been developed (table 16). For example, 52 aquifer-type reservoirs were in use in 10 States at the end of 1975. Illinois was the leading State with 22, and Indiana ranked second with 10. Aquifer storage accounted for 22% of total underground storage capacity at year-end 1975. The increase in aquifer reservoir capacity during the year was negligible.

The development of underground storage reservoirs has been an important factor in meeting peak natural gas demand, particularly in the residential house-heating market, in which there is a high degree of seasonal variation. There is a concentration of underground storage facilities relatively close to the largest markets for residential heating. Illinois had 675 Bcf of natural gas stored in 31 reservoirs, and Pennsylvania had 608 Bcf stored in 68 reservoirs at the end of 1975. The two States accounted for 30% of the total stored gas in underground reservoirs.

In 1975, the total amount of gas moved into underground storage totaled 2,104 Bcf (table 17). During the same period, 1,760 Bcf was withdrawn, leaving a net stored of 344 Bcf for the year.

In addition to underground storage, there has been a marked growth in the aboveground storage of natural gas that has been liquefied by reducing its temperature to −258° F (−161° C). LNG occupies only 1/620th the space necessary for conventional vapor storage. LNG storage is used for peak-shaving purposes during the high-consumption low-temperature winter months.

The following tabulation summarizes LNG storage data:

Facility	Status	Capacity (Bcf)	Number of plants
Peak-shaving	Operational	49.7	51
Do	Under construction	9.4	8
Large satellite	Operational	5.2	20
Do	Under construction	2.5	3
Small satellite	Operational	.2	31
Import-receiving terminals	Do	11.2	3
Do	Under construction	9.0	2
Total	Operational	66.3	105
Total	Under construction	20.9	13

VALUE AND PRICE

Total wellhead value of marketed natural gas production increased 36.1% to $8,945 million in 1975, despite a 6.9% decline in production volume (table 18). This occurred as a result of a 46.4% increase in average wellhead value to 44.5 cents per Mcf. Texas and Louisiana accounted for 56.7% and 26.1%, respectively, of the $2,372 million increase in total value during 1975.

Wholesale Prices.—Average wholesale prices for natural gas in the 14 large metropolitan areas for which FPC collects such data rose substantially between July 1, 1974, and July 1, 1975. Increases for individual areas ranged from 15.7% to 92.3%, and the median price rise was 30.8%. Wholesale prices as of July 1, 1975, ranged from 67.93 cents per Mcf in the Minneapolis-St. Paul area to 133.14 cents per Mcf in the Boston area.

A 7-year historical series of average wholesale natural gas prices in the 14 large metropolitan areas is shown in table 19. The wholesale prices for gas in those cities cited are based on the effective FPC gas tariffs. In cities served by more than one pipeline, prices are based on weighted-average charges. Prices reflect deliveries at the city gate except for Los Angeles and San Francisco, where distributors purchase gas at the California-Oregon and California-Arizona State lines.

Retail Prices.—The average retail price for natural gas delivered to all classes of consumers increased 33.4% from 89.4 cents per Mcf in 1974 to 119.3 cents per Mcf in 1975. Monthly data, collected by the Bureau of Labor Statistics on the average price of residential heating gas for 20 standard metropolitan areas, indicate an average increase of 40.9% between January 1975 and January 1976. Increases for individual areas during the same period ranged from only 5.0% in Buffalo to 65.4% in Dallas and 48.7% in Houston, where much of the current supply is obtained under relatively recent, high-priced intrastate contracts. A historical summary of average residential heating gas prices in 20 standard metropolitan statistical areas appears in table 20.

FOREIGN TRADE

Exports of natural gas totaled 73 Bcf in 1975, a decline of 5.4% from 1974. Of the total 1975 volume, 72.9% was shipped from Port Nikiski, Alaska, to Japan as LNG. Exports via pipeline to Canada and Mexico were almost equally divided, with Canada receiving 51.9% of the total deliveries.

The LNG exported to Japan in 1975 totaled 53.0 Bcf valued at $73 million, compared with 50.3 Bcf valued at $37 million in 1974. The Alaskan LNG was exported rather than shipped to the lower 48 States since no receiving terminals exist on the U.S. west coast and there are no U.S. flag LNG tankers capable of transporting LNG from Alaska to the east coast. Federal Maritime law requires U.S. flag ships for all interstate seaborne trade. Statistics on LNG exports for 1975 are shown in table 21.

Exports via pipeline to Canada in 1975

totaled 10.2 Bcf, compared with 13.3 Bcf in 1974, a decline of 22.9% (table 22). Detroit was the exit point for most of these exports. Natural gas exports via pipeline to Mexico continued to decline from 13.3 Bcf in 1974 to 9.5 Bcf in 1975.

Pipeline imports of natural gas from Canada declined in 1975 to 948 Bcf, a decrease of 1.1% from those of 1974. These imports were valued at $1,147 million, more than double the 1974 total of $531 million. The rapid increase in value is reflected in the average price of gas from 55.35 cents per Mcf in 1974 to 121.03 per Mcf in 1975. Nine companies imported Canadian gas in 1975. For the first time since 1955 there were no imports of natural gas from Mexico.

Algeria, the only source of LNG imports during 1975, shipped a total of 4.9 Bcf valued at $3.6 million to Everett, Mass., the U.S. receiving point. There were no LNG imports from Canada in 1975.

The El Paso Natural Gas Co.'s 25-year contract with Société Nationale pour la Recherche, la Production, le Transport, la Transformation et la Commercialisation des Hydrocarbures (SONATRACH), the Algerian National Oil and Gas Company, which has been approved by FPC, calls for the delivery of LNG, equivalent to 1 Bcf per day. A fleet of nine tankers owned and operated by a subsidiary of El Paso will transport the LNG from Algeria to receiving terminals under construction at Cove Point, Md. and Elba Island, Ga.

The LNG receiving terminal under construction at Cove Point, Md., which is jointly owned by Columbia Gas System and Consolidated Natural Gas System, was about 50% complete at yearend 1975. Deliveries of LNG from El Paso Natural Gas Co. are expected to begin in late 1977. Initially, the terminal, with four storage tanks, will handle 650 MMcf (million cubic feet) of gas per day with 300 MMcf per day going to Columbia, and Consolidated receiving 350 MMcf per day. An area has been set aside for two more tanks when additional storage will be needed for future requirements. After being regassified at Cove Point, the gas will be shipped via an 87-mile pipeline being laid to a compressor station on Columbia's gas transmission system at Loudoun, Va.

Construction on the LNG receiving terminal on Elba Island near Savannah, Ga., owned by Southern Energy Co., was about one-third complete at yearend 1975, and is scheduled for completion in 1977. Southern will receive 350 MMcf of gas per day from El Paso.

Other proposed LNG projects are awaiting FPC approval.

WORLD REVIEW

World marketed production of natural gas continued to increase during 1975 when it totaled 47.2 Tcf (table 25). The United States accounted for 20.1 Tcf, or 42.6% of this total.

Algeria.—Marketed production in Algeria totaled 210 Bcf in 1975, an increase of 5.8% compared with that of 1974. Nearly all marketed natural gas production was exported as LNG.

Algeria's state-owned company SONATRACH cancelled a contract in November 1975 with Chemical Construction Corp. in a performance dispute over construction of the Arzew No. 1 gas liquefaction plant. Bechtel International, Inc., was named to complete the project. SONATRACH expects deliveries of LNG from this plant, which will be exported to the United States.

Algeria, Spain, and France jointly established the Segamo Co. to make economic feasibility studies on a proposed trans-Mediterranean pipeline to deliver gas from Algeria's Hassi R'Mel field to Western Europe.

Canada.—Marketed production in Canada, which ranked fourth in total output, totaled 3.1 Tcf in 1975, an increase of only 1% over that of 1974. More than 85% of total Canadian production came from the Province of Alberta, with British Columbia accounting for most of the remainder. Exports to the United States totaled 948 Bcf, about 30.8% of total production.

Canada's total proved gas reserves of 57 Tcf at yearend 1975 remained about the same as in 1974. Exploration in the Canadian Arctic continued to decline. This was due in part to the uncertainty of Government energy policies and extremely high operating costs.

In 1975, Sun Oil Co., Ltd., drilled a gas discovery well on Garry Island, just off the Mackenzie Delta. Tests yielded gas flows at rates up to 17 MMcf per day.

Commercial development is planned for three fields in the Mackenzie Delta area, Imperial Taglu, Gulf-Mobil Parsons, and Shell Niglintgak. Gulf Oil Canada, Ltd., has awarded a contract for engineering and design, to include a gathering system, support facilities, and a 300-MMcf-per-day gas-processing plant at the Parsons Lake field. Shell Canada, Ltd., plans a 150-MMcf-per-day processing plant at Niglintgak.

Applications from two separate consortia for the right to construct pipeline facilities that would transport Mackenzie Delta gas to market were before the National Energy Board at yearend 1975. Canadian Arctic Gas Pipeline, Ltd., a consortium of U.S. and Canadian companies, was seeking permission to construct a pipeline that would transport both Mackenzie Delta and northern Alaska gas. Foothills Pipe Lines, Ltd., a partnership between Alberta Gas Trunk Line Co., Ltd., and Westcoast Transmission Co., Ltd., was advocating the construction of a line (Maple Leaf Pipeline) that would transport only Canadian natural gas from the Mackenzie Delta.

There have been seven significant gas discoveries to date in the Arctic Islands with estimated reserves totaling 15 Tcf. Drake Point and Hecla, the two largest discoveries, are located on the Sabine Peninsula of Melville Island. The remaining five are clustered in the Ellef Ringnes Island area.

During 1975 the Polar Gas Project, under the management of TransCanada Pipelines, Ltd., continued to conduct research on the construction of a natural gas pipeline from the Canadian Arctic to southern Canada. Studies indicate a transmission system is technologically feasible. Investigation was expected to continue throughout 1976.

Netherlands.—The Netherlands, Western Europe's largest natural gas producer and exporter, displaced Canada as the world's third ranking natural gas producing country during 1975. Marketed production totaled 3.2 Tcf an increase of 8.5% over that of 1974, with the onshore Groningen field producing the largest share.

Offshore exploration and development in the Netherlands was increased during 1975, partly because of the Government's decision to acquire a 40% interest in these operations. The first gas deliveries from the North Sea began in mid-1975 upon completion of a 110-mile, 36-inch pipeline. Initially, 100 MMcf per day was brought ashore but this was expected to climb rapidly, with annual production expected to reach 70 Bcf in 1976. Half of the gas will go to West Germany under a 24-year contract.

In an effort to slow down the growth of energy consumption, the Netherlands Government has approved plans to gradually phase out gas sales to electric power stations and large factories after 1978. Priority will be given to small consumers. Exports will start to decline after 1978 and will virtually cease after 1994 because no new export contracts will be granted.

Norway.—Most of Norway's proved reserves at yearend 1975 were in the offshore Ekofisk and Frigg oil and gas fields. Deliveries of natural gas through a 274-mile pipeline from the Ekofisk field to Emden, West Germany, were scheduled to begin in the last half of 1976. Development of the giant Frigg gasfield in the North Sea was expected to be delayed at least 2 years because efforts were abandoned to salvage a $50 million drilling platform jacket that sank during installation.

Romania.—The 1975 marketed production in Romania was estimated at 954 Bcf, a decrease of 5.7% from that of 1974. Most of the gas produced was used domestically. Although exploration and development drilling continued in the Ploiesti-Focsani oil and gas district, indications were that future exploration would be concentrated in the Black Sea area. An agreement was signed with Italy's State-owned Ente Nazionale Idrocarburi (ENI) for future joint exploration in the Black Sea.

United Kingdom.—North Sea oil and gas activity was at the higest level in its 12-year history during 1975. Although more exploration programs were in progress than at any other time, by mid-1975 emphasis was turning toward development and production. Brent oil and gas field, the largest in the United Kingdom's waters, with gas reserves of 3 Tcf, and 2,000 million barrels of oil, was expected to be the world's most northerly producing offshore field in the open sea when production was scheduled to begin in 1976. In June 1975, British Gas Corp. signed a 20-year contract for natural gas from Brent field. The gas will flow at a minimum of 500 MMcf per day from a 300-mile 36-inch pipeline to St. Fergus, Scotland. Deliveries are expected to begin in 1980. The southern North Sea supplies about 30% of the total gas consumed in the United Kingdom.

U.S.S.R.—The U.S.S.R. was second to the United States accounting for 21.6% of world production Its 1975 marketed production was estimated to have been 10.2 Tcf, an increase of 10.9% over that of 1974. Exports of natural gas, mostly to Eastern European countries, climbed to a record high of more than 600 Bcf in 1975, compared with 496 Bcf in 1974.

An agreement was signed in 1975 with Iran involving the exportation of Iranian natural gas to Western Europe by means of an exchange arrangement. Iran will export 473 Bcf per year for consumption in the industrial centers of southwestern U.S.S.R. under terms of the agreement. The U.S.S.R. in turn, will pipe Siberian gas to Iran's West European customers—West Germany, France, and Austria. Deliveries are scheduled to begin in 1981 and continue for 20 years.

Natural gas production in western Siberia climbed to 1.3 Tcf in 1975, with the Medvezhye field in Tyumen Province accounting for about 88% of this total. Urengoiskoye, the U.S.S.R.'s largest gasfield, with estimated reserves of 178 Tcf, located 60 miles east of Medvezhye, is scheduled for production in 1977. Most of the U.S.S.R.'s gas reserves are located in western Siberia, near or above the Arctic Circle.

TECHNOLOGY

The shortage of natural gas continued to stimulate Government and industry research in coal gasification. Three pilot projects for development and testing of processes for the production of high-Btu gas from coal were operational, and three others were under construction at yearend 1975. A pilot project involving the production of low-Btu gas from coal was also operational, and two others were under construction as of the same date. During the latter part of 1975, the Energy Research and Development Administration (ERDA) was in the process of preparing invitations for proposals covering the design, construction, and operation of high-Btu and low-Btu coal gasification demonstration plants. These facilities would provide the final development step prior to the construction of a commercial plant.

The Bureau of Mines continued its experiment in gathering methane from a coal deposit near Bula, W. Va. This project drained approximately 220 MMcf from a coalbed through a large air shaft during 1975. Some of the drained methane was sold to Consolidated Gas Supply Corp. for delivery to a nearby community. This experiment was being carried out with a dual purpose. To provide additional natural gas supplies for distribution; and to reduce coal mining hazards.

Efforts to supplement natural gas supplies through the gasification of naphtha and natural gas liquids continued. As of yearend 1975, a total of 11 such synthetic gas plants were operational, 2 were under construction, and 2 were in the planning stage.

Other gasification projects in progress involved biomass conversion. During 1975, Los Angeles County began the recovery of methane from the Palos Verdes sanitary landfill in cooperation with NRG NuFuel Inc. and Reserve Oil & Gas Co. This project is expected to yield 2 Bcf of pipeline-quality gas annually. In addition, projects for the production of pipeline-quality gas from animal waste by the process of anaerobic digestion were in various stages of development in Colorado, Oklahoma, and Texas.

In addition, to gasification projects, research has also focused on fracturing techniques that stimulate flow from economically submarginal gas reservoirs. Most of this activity was in Wyoming, Colorado, and Utah, but one major project initiated during 1975 involved the massive hydraulic fracturing of Upper Devonian gas shales in Mingo County, W. Va. These shales underlie about 12 Eastern States, including those that comprise the major northeastern markets, and are estimated to contain producible gas that may exceed the Nation's total current proved reserves. The U.S. Geological Survey is to provide coordination and assistance in the resource assessment activities of the program.

During 1975, the U.S. Geological Survey studied the methane-saturated Gulf coast salt water aquifers penetrated by 193 wells in Texas and Louisiana. On the basis of this study, the Survey estimated that these aquifers in onshore reservoirs alone may contain up to 24,000 Tcf of methane.

Table 2.—Gas pipeline failures reported during 1974–75

[1] Includes multiple completion wells that produce gas from all zones.

[2] Includes multiple completion wells that produce gas from one or more zones but oil from at least one zone.

[1] The net difference between gas stored in and gas withdrawn from underground storage reservoirs, inclusive of adjustments and native gas transferred from other reserve categories. (Adjustments include change of reporting basis starting in 1974 to report only gas reserves considered recoverable, in effect, reducing gas reserves by 1,024,140 MMcf that would have been reported since 1972 using the former basis.)

[2] Preliminary net production.

[3] Proved recoverable gas contained in underground gas storage reservoirs, including native and net injected gas. (First reported on a recoverable basis in 1973.)

[4] Includes offshore.

[5] Reported quantities include reserves estimated to be recoverable from some reservoirs considered natural gas bearing based on electrical logs, core data and other available engineering and geological data.

[6] Included with Louisiana and Texas.

Source: Committee on Natural Gas Reserves, American Gas Association.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Thailand produces crude oil and presumably produces natural gas but available information is inadequate to estimate output levels.

[2] Comprises all marketed production (see footnote 3) plus gas vented, flared, reinjected for repressuring or for storage and used to drive gas turbines without being burned.

[3] Comprises all gas collected and utilized as a fuel or as a chemical industry raw material as well as that used for gas lift in fields, including gas used in oilfields and gasfields as a fuel by producers, even though it is not actually sold.

[4] Gas vented or flared is apparently not included; difference between gross production and marketed production is the amount reinjected into reservoirs.

[5] Gross production not reported, marketed output has been reported in lieu of estimating gross output because the quantity vented, flared or reinjected is believed to be small.

[6] Includes output from coal mines as follows, in million cubic feet: Austria: 1973—71, 1974—71, 1975—70 (estimate); Czechoslovakia: 1973—11,159, 1974—10,806, 1975—10,500 (estimate); West Germany: 1973—21,577, 1974—17,940, 1975—16,000 (estimate); the Netherlands: 1973—671, 1974 and 1975—0; Poland: 1973—7,628, 1974—7,451, 1975—7,400, (estimate); the United Kingdom: 1973—4,484, 1974—3,991, 1975—3,800 (estimate); Japan: 1973—10,806, 1974—9,747, 1975—9,500 (estimate).

[7] Total production is obtained from coal mines.

[8] No marketed production reported; there probably is some small field use in Denmark, Norway and Sharjah, and in Norway there was extraction of natural gas liquids reported in each year 1973–75, but available information is inadequate to permit reliable estimation of output levels.

[9] Includes gas reinjected to reservoirs, if any.

[10] Excludes gas used for gas lift.

[11] Data are for year ending June 30 of that stated.

[12] Includes ½ of production reported for the former Kuwait-Saudi Arabia Neutral Zone.

Natural Gas Liquids

By Thomas G. Clarke [1] and Leonard L. Fanelli [2]

Domestic production of natural gas liquids (NGL) from gas processing plants in 1975 was 596 million barrels, down 20.1 million barrels, or 3% from 1974 production. This was the third consecutive annual decline in NGL output. The value in 1975 fell to $2.77 billion from $3.09 billion in 1974. This represented a decrease in average unit value to $4.65 from $5.01 per barrel in 1974. This was a result of the Government's mandatory allocation program administered by the Federal Energy Administration (FEA). The establishment of new base prices by FEA early in 1975 resulted in a lower average unit value than in the previous year. On an individual basis, the base prices were adjusted to include product and nonproduct costs and shrinkage.

Total natural gas processed for liquids decreased 5% to 17.7 trillion cubic feet from 18.7 trillion cubic feet a year earlier. Decreased production of natural gas liquids during the year resulted from a decline in the availability of natural gas for processing. A mild winter season and an economic recession in 1975 contributed to an increase in yearend total NGL stocks to 124 million barrels compared with 114 million barrels in 1974.

Presidential Proclamation 4317, dated September 24, 1974, provided for the tariff on NGL imports (excluding propane) to increase to 18 cents per barrel from 15.5 cents per barrel, effective May 1, 1975. However, Presidential Proclamation 4341, dated January 23, 1975, established a tariff of 21 cents per barrel on NGL imports (excluding propane) effective February 1, 1975. No further change was made during the remainder of the year.

Natural gas liquids are products obtained from processing natural gas at natural gas processing plants. Products recovered are ethane, liquefied petroleum gases (LPG—butane, propane, pentane, and butane-propane mixtures), isobutane, and mixed gases. Other products are natural gasoline, plant condensate, and at plants equipped with fractionators, finished products such as gasoline, naphtha, jet fuel, kerosine, distillate fuel oil, and other products.

Data presented in this chapter were compiled from reports of plants that process natural gas. Plant condensate is included in NGL; field condensate is included with crude oil data found in the Petroleum chapter. Ethane and liquefied gases recovered from crude oil refinery operations (such as ethane, butane, and propane) are classed as liquefied refinery gases (LRG) and are reported as refined petroleum products.

[r] Revised.

[1] Includes isopentane, plant condensate, finished gasoline, special naphtha, distillate fuel oil, kerosine, and miscellaneous.

[2] Includes 93,595 million barrels in underground storage.

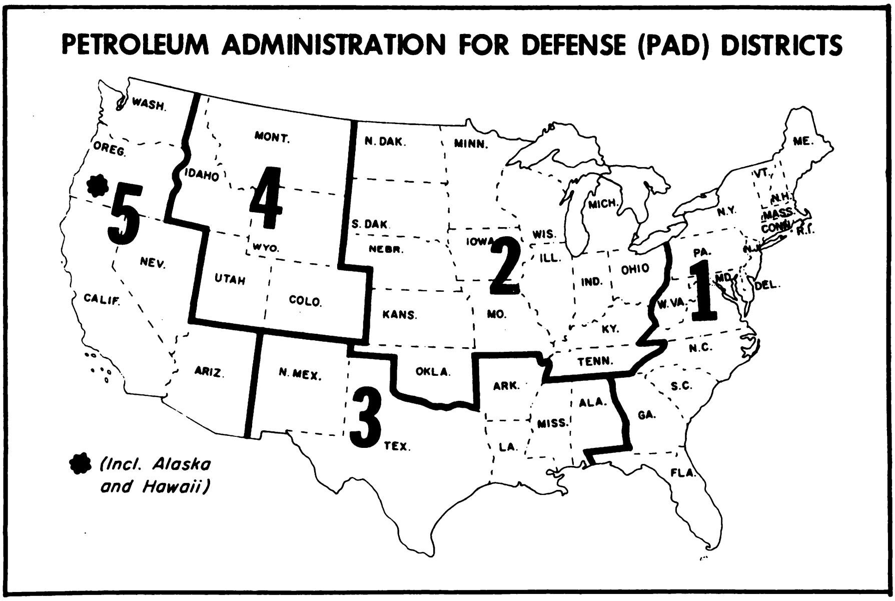

Figure 1.—Map of PAD districts.

DOMESTIC PRODUCTION

NGL production in 1975 was 596 million barrels, down 20.1 million barrels, or 3% from 1974 production. Output of all categories declined except ethane, which posted a 4.4% gain over that of 1974. Demand for ethane as a petrochemical feedstock, primarily for use in ethylene manufacture, caused NGL processors to take deeper cuts in gas throughput for increased ethane recovery. The following tabulation shows the quantity and percent change between 1974 and 1975 of major NGL groups:

	Thousand barrels	Percent
Ethane	+5,154	+4.4
LPG:		
Propane	−5,966	−2.9
Other	−3,034	−2.5
Natural gasoline and isopentane	−13,305	−9.0
Other natural gas liquids	−2,835	−13.6
Total	−20,140	−8.3

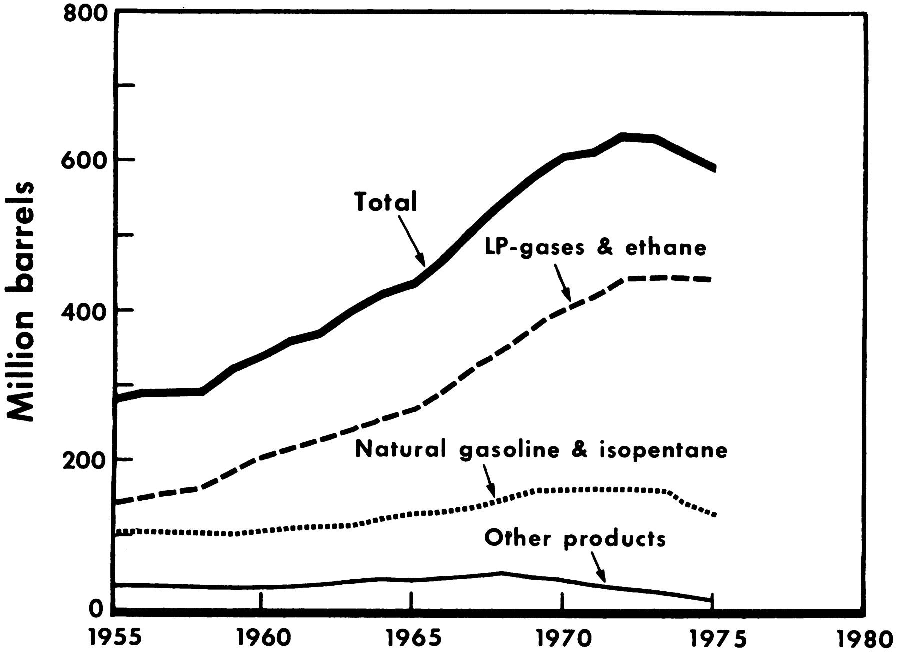

Figure 2.—Production of natural gas liquids in the United States.

Plant throughput capacity at yearend 1975 was 72.7 billion cubic feet of gas per day, down almost 2% from 73.9 billion cubic feet per day in 1974.[3] The number of gas processing plants in operation also declined by 9 to 754 at yearend 1975 as a result of the phaseout of processing plants in depleted field areas. These plants were located in 24 States and owned and/or operated by 130 companies. Production from gas processing plants was centered in Texas, 49%; Louisiana, 23%; Oklahoma, 7%; California and Alaska, 2%; New Mexico, 7%; and other, 12%.

RESERVES

The American Gas Association (AGA) estimated total proved reserves of natural gas liquids in the United States in 1975 at 6,268 million barrels. This was a decrease of 82.6 million barrels, or 1% from 1974. The decrease in 1975 was the eighth consecutive year of declining proved reserves. Approximately 56% of total reserve additions during the year were accounted for by revisions, 21% were discoveries, 19% were extensions, and 4% were new reservoirs in oilfields. Production to reserve ratio in 1975 was 8.6 to 1 compared with 8.8 to 1 in 1974.

Of total domestic natural gas liquid reserves, Texas accounted for 42%; Louisiana, 27%; Kansas, 7%; New Mexico, 6%; and others, 68%. While total U.S. reserves decreased in 1975, Alabama and Colorado reported significant increases from 1974 reserve totals of 133.1 and 41.1 million barrels, respectively.

---

[3] Oil and Gas Journal. V. 74, No. 27, July 5, 1976, p. 67.

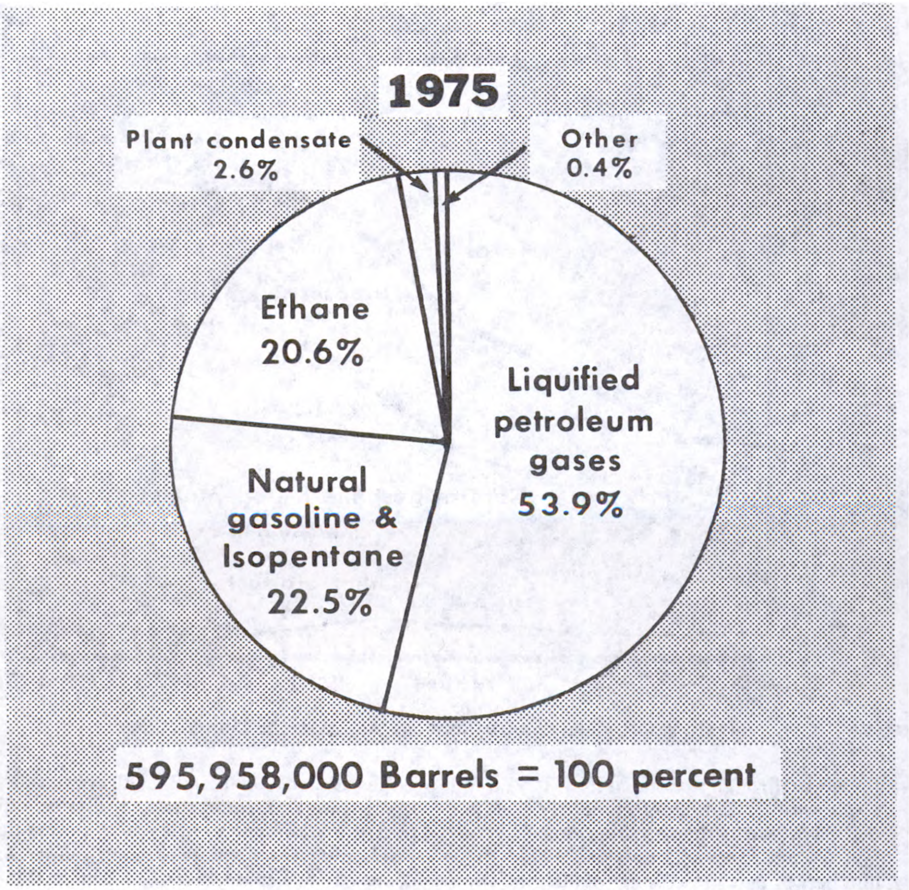

Figure 3.—Relative production of natural gas liquids components, 1975.

CONSUMPTION AND USES

In 1975, almost 44% of NGL output was used by refineries. Total input of liquids was 259.3 million barrels, a decrease of 5% compared with that in 1974. The decrease resulted primarily from a 9% drop in refinery input of natural gasoline and a 20% drop in plant condensate. Most other product categories posted minor gains. The following summary shows shipments (input) to refineries in thousand barrels:

	1974	1975	Change (percent)
Propane	3,465	3,926	+13.3
Butanes:			
Isobutane	30,829	35,760	+16.0
Normal butanes	29,110	35,056	+20.4
Other butanes	13,855	13,647	−1.5
Total butane	73,794	84,463	+14.5
Butane-propane mixtures	2,958	1,273	−57.0
Natural gasoline	147,603	134,087	−9.2
Isopentane	--	--	--
Plant condensate	44,596	35,570	−20.2
Grand total	272,416	259,319	−4.8

Domestic demand for liquefied gases and ethane at gas processing plants in 1975 was 375.5 million barrels, down from 387.7 million barrels in 1974. At refineries, demand for liquefied refinery gases (LRG) was 78.1 million barrels for fuel use and 32.8 million barrels for chemical use. Total domestic demand for LPG and LRG in 1975 was 486.4 million barrels compared with 512.8 million barrels in 1974.

Propane demand (including propylene), which accounts for 59% of total demand, was 285.9 million barrels in 1975 compared with 303.1 million barrels in 1974. Plant demand for propane during 1975 was 202.5 million barrels and refinery propane and propylene demand was 83.3 million barrels, 74% of which was for fuel use and the remainder was for chemical use. Domestic demand for butane (including butylene) decreased to 67.3 million barrels in 1975. Plant demand was 50.4 million barrels and refinery demand was 16.9 million barrels.

Domestic demand for ethane totaled 124.5 million barrels in 1975, about the same as in 1974. The output of ethane is utilized, almost in its entirety, as petrochemical feedstocks. Total production of ethylene from ethane in 1975 was 19.8 billion pounds, according to the U.S. International Trade Commission statistics. Production in 1974 was at an alltime high of 23.5 billion pounds.

Total sales of LPG and ethane were 24.6 billion gallons in 1975, down 2.7% from that in 1974. Propane constituted about 50.3% and ethane about 21.3% of the 1975 total. Approximately 38% of 1975 sales were to the chemical industry, 29% to residential and commercial users, and 15% for use in gasoline production.

STOCKS

Record levels of NGL and ethane stocks at yearend 1975 reflected a warmer than usual winter season across the United States. Total stocks reached a historic high of 140.3 million barrels on September 30, 1975. The total had decreased to 124.3 million barrels by December 31, up 8.7% from yearend 1974. These stocks included 93.6 million barrels in underground storage. Stocks at NGL plants and terminals at yearend 1975 were 118.2 million barrels, up 9.8 million barrels from that in 1974, whereas those at refineries were 6.1 million barrels, up only 146,000 barrels from 1974. The increase in stocks at NGL plants and terminals consisted principally of propane, 7.6 million barrels, and ethane, 2.5 million barrels; major reductions were in butane, 3 million barrels, and natural gasoline, 100,000 barrels.

PRICES AND VALUE

The average unit value of NGL production at natural gas processing plants in 1975 was $4.65 per barrel, down 36 cents, or 7% from the 1974 average. The total value of NGL production was $2.77 billion compared with $3.09 billion in 1974. This was a result of FEA mandatory allocation and price controls. The establishment of new base prices resulted in the lower 1975 average unit value. A tabulation of average prices, from 1971–75, in dollars per barrel, follows:

	1971	1972	1973	1974	1975
LPG and ethane	1.84	1.91	2.66	4.42	4.26
Natural gasoline and isopentane	3.00	3.06	3.51	6.59	5.81
Plant condensate	3.37	3.39	3.94	6.52	5.47
Finished gasoline and naphtha	4.34	4.66	4.29	7.97	7.76
Other [1]	2.62	2.58	3.25	5.39	5.35
Total	2.24	2.28	2.93	5.01	4.65

[1] Includes kerosine, distillate fuel oil, and miscellaneous products.

Yearend propane prices were higher than in 1974 because of the increased cost of natural gas as well as throughput costs. Propane price data for New York Harbor; Baton Rouge, La.; Oklahoma; Mt. Belview, Tex.; Wood River, Ill., and Los Angeles are presented in table 17.

FOREIGN TRADE

LP gases and plant condensate imports decreased 12.5% in 1975 to 67.7 million barrels from 77.3 million barrels in 1974. Lower demand for these imports was attributed to the recession in domestic economic activity and a warmer than usual winter season. Despite this decline, LPG and condensate imports ranked second, on a volume basis, in order of importance among liquid hydrocarbon product imports behind residual fuel oil. Plant condensate imports were delivered primarily for use as feedstocks in synthetic natural gas plants located in Ohio and Michigan.

Canada supplied all imports of plant condensate and 74% of the LPG imports. Venezuela and Saudi Arabia supplied 12% and 7% of LPG receipts, respectively. Other countries exporting more than 100,000 barrels per year to the United States were Kuwait, Algeria, and France. Total value of LPG imported in 1975 decreased to $354.9 million from $365.1 million in 1974.

Exports of LPG from the United States increased slightly to 9.4 million barrels. Traditionally, Mexico was the leading importer of U.S. LPG products, mostly butane-propane mixtures for consumption in residential heating and cooking. Mexico received 97% of total LPG exports, or 9.2 million barrels. Algeria received 2% or 166,000 barrels. Total value of exports increased to $100 million, up $5.6 million from 1974.

A breakdown of LPG exports by type was as follows: Butane, 6%; propane, 23%; and butane-propane mixtures, 71%.

WORLD REVIEW

The United States and Canada produced 69% of the total world production of NGL in 1975. Saudi Arabia, Kuwait, and Iran produced a combined estimated total of 82 million barrels, or about 8% of the total. Largest increases in production during the year were in these three Middle East countries.

The Government of Dubai, one of the Arab Emirates, finalized a venture with a Canadian firm, Sunningdale Oils, Ltd., for the construction of an NGL plant for processing of all gas produced in that country. Construction of the $200 million complex began in May. This plant's planned annual throughput of 36.5 billion cubic feet of gas will yield about 5.1 million barrels of liquids.

The Government of Kuwait awarded $60 million in contracts to four U.S. companies for the construction of seven turbine and compression stations for a NGL plant. The plant is scheduled for operation in December 1977 and is to have an annual capacity of 402 million barrels of LPG and natural gasoline.

The Oil Service Company of Iran has contracted with a U.S. firm to build a gas-processing plant in southern Iran at an estimated cost of $500 million. The plant, which is to include facilities for gas compression and processing, will be in the Ahwaz Marun oilfield. Operation of this plant is scheduled to begin in 1978 and the NGL output will be used as petrochemical feedstocks and fuel for consumption in Iran.

The Government of Saudi Arabia and the Arabian American Oil Co. (Aramco) have initiated construction of five NGL centers for the processing of associated gas from oilfield production. Each center is designed for a throughput of about 1.5 billion cubic feet of gas per day. The peak output of the center is expected to be about 554,000 barrels per day by 1979.

Offshore activity and increasing gas production in Australia's Bass Strait area have prompted the expansion of onshore NGL facilities. The capacity of a plant at Longford will be doubled to 670 million cubic feet of gas per day. In the Long Island Point fractionation plants at Westport, capacity will be increased from 43,500 barrels of propane-butane and 9,000 barrels of ethane per day to 58,800 and 12,500 barrels per day, respectively.

The Nigerian Government approved the construction of an LPG complex, designed to process 1 billion cubic feet per year of natural gas now being flared in the country's oilfields.

Construction of a gas treatment plant at Emden, West Germany, was nearing completion at yearend 1975. With an initial throughput capacity of 1 billion cubic feet of gas per day, the plant was scheduled to go onstream late in February 1976. The gas processed will come from the Ekofisk area of the Norwegian sector in the North Sea. Planned construction scheduled in 1977 will increase plant throughput capacity to 2.2 billion cubic feet of gas per day. This would be the largest capacity of any natural gas-processing plant in the world.

Construction continued on the world's first open sea offshore NGL plant located about 90 miles northeast of the city of Jakarta and 20 miles off the coast of Java. At the end of 1975, construction of the plant was about 75% complete. The complex will consist of seven offshore platforms in over 100 feet of water. Included are quarters for 150 men, 4 gas compression platforms, and 2 platforms for processing and stabilization of crude oil. Throughput of natural gas will be up to a rated capacity of 230 million cubic feet per day. The heavier NGL recovered will be added to the 125,000 barrels-per-day output of crude oil. The plant is scheduled to go onstream in mid-1976.

TECHNOLOGY

A new LPG recovery process has been developed for the extraction of high percentages of propane and heavier fractions from natural gas when the feedstock pressure (natural gas) is higher than 800 psi and the returned dry gas requires a similar pressure. The new absorption process allows separation without pressure reduction and subsequent repressuring for dry gas delivery. This results in considerable power conservation. Nearly 100% butane and 90% propane recovery can be economically achieved. The plant process can be used in remote locations because of its self-contained process cycle. About 2% to 3% of the methane is used as fuel. Propane is used as the cycle refrigerant and natural gasoline as the absorption oil.

The Warren Petroleum Inc., a subsidiary of Gulf Oil Corp., has developed a highly portable NGL extraction plant. Recovery from 0.1 to 10 million cubic feet per day throughput yields 65% to 75% of the propane and most all of the heavier components contained in the gas. For larger volumes of gas throughput, the processing plant is able to recover up to 76% of the ethane, 99% of the propane, and ail of the heavier components. The plant is totally electric.

Computer control systems have become regular installations in all newly constructed domestic NGL plants. These systems control the process flow rates, provide an accurate analysis of product streams for quality control, enhance the recovery of liquids, and control precisely the processing variables.

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the countries listed, the People's Republic of China may also produce natural gas liquids, but information is inadequate to make reliable estimates of output levels. Every effort has been made to include in this table only those natural gas liquids produced by natural gas processing plants, and to exclude natural gas liquids obtained from field treatment facilities including wellhead separators, because the latter are normally blended with crude oil and thus are in statistics on crude oil output. In some cases, however, sources do not clearly specify whether data presented represent only output of natural gas processing plants or if they include field output. Thus, some of the figures in this table may include field condensate. Where this appears to be the case, the country has been so footnoted, but it may also be true in the case of other countries.

[2] May include field condensate.

[3] Total of listed figures only, and as such represents an incomplete total, due to the fact that in the case of some countries, only the total of butane and propane or only total natural gas plant liquids are reported in sources, and insufficient data are available to estimate the distribution of the totals by individual type. Summation of totals of propane and butane thus does not equal the reported natural gas plant liquid total.

Nickel

By John D. Corrick [1]

The tight nickel supply that developed at yearend 1974 quickly changed into an oversupply situation in 1975 as the industrial economies of the world slowed down. The surplus nickel supply had little effect upon new developing nickel operations, although Falconbridge Nickel Mines, Ltd. (Falco), reduced their capacity by about 30% during the latter part of 1975. The supply base for nickel continued to expand with new mining and processing operations beginning in the Philippines, Australia, Botswana, and the United States.

Domestic nickel consumption decreased in 1975 by nearly 30% from the record high consumption in 1974 and resulted in record high inventories of consumer-held nickel during 1975. The surplus supply situation was compounded by decreased demand for nickel and the simultaneous startup of several new nickel operations worldwide. Nevertheless, the surplus could have been more pronounced had it not been for startup troubles at most of the new operations. The pattern of nickel consumption was little changed from previous years. For the first time in several years ferronickel failed to increase its share of the total primary nickel consumed in the United States.

The price of cathode nickel was increased 19 cents per pound on August 29 by International Nickel Co. of Canada, Ltd. (INCO). Similar price increases were made in domestic and foreign produced ferronickel in September. Consumer price protection, at the old prices, was in effect until December.

World trade in nickel was set back by the general slowdown in industrial economies. Imports of nickel into the United States in 1975 were down nearly 27% when compared with those in 1974. Japanese importers of nickel requested reductions in nickel ore import quotas agreed upon in 1974 from New Caledonia and Indonesia because of a slack demand for stainless steel.

DOMESTIC PRODUCTION

The level of activity by domestic nickel producers increased in 1975 over that of 1974 as a result of the startup of the AMAX Inc. renovated nickel-copper-cobalt refinery in Louisiana, although the refinery operated well below capacity. According to the AMAX annual report the refinery produced 8,000 short tons of nickel during the first year of operation.[2] The one domestic nickel mine, operated by Hanna Mining Co. at Riddle, Oreg., produced 16,987 tons of nickel from laterite ore, as measured by mine shipments. Nickel recovered at the Hanna smelter and byproduct nickel salts and metals produced at copper and other metal refineries amounted to 14,343 tons; part of the byproduct originated from scrap. Exploration for nickel in 1975 continued in Minnesota, Oregon, California, and Montana. Major exploration interest was centered in Minnesota. The two principal firms interested in developing nickel mining in Minnesota were INCO and AMAX (Minnamax). At yearend, officials of INCO announced that they would suspend further activity on their nickel-copper mining project near Ely, Minn. The proposed changes in State policy toward nickel-copper development were the reasons given for suspension of work. On the other hand, AMAX Exploration Inc. requested and received permission to develop a test mine shaft near Babbitt, Minn. AMAX began construction of surface facilities required for the underground exploration phase in November. The test shaft will be 14 feet in diameter and 1,710 feet deep. AMAX hoped to obtain a 5,000-ton bulk sample of ore for metallurgical testing. Universal Oil Products Co. (UOP) announced plans to construct a $2 million demonstration plant at Tucson, Ariz. Construction was to begin in the fall of 1975. The plant will test UOP's new hydrometallurgical process for treating lateritic ores. Designed throughput of the plant was to be 5 tons per day of ore resulting in the production of 150 pounds per day of high-purity nickel.

UOP officials held discussions with Puerto Rican officials during 1975 on the possibility of the company developing nickel deposits near Guanajibo, Puerto Rico. Puerto Rican ore reserves have been estimated at 375,000 tons of contained nickel, sufficient to support a 30-million-pound-per-year operation for 25 years. Puerto Rican laterites have been tested by UOP on a laboratory scale and would probably be one of the first ores to be tested in the new pilot plant.

(Short tons)

Kind of scrap	1974	1975
New scrap:		
Nickel-base	1,054	3,123
Copper-base	4,224	5,222
Aluminum-base	627	1,251
Total	5,905	9,596
Old scrap:		
Nickel-base	14,040	7,825
Copper-base	598	375
Aluminum-base	387	84
Total	15,025	8,284
Grand total	20,930	17,880

Form of recovery	1974	1975
As metal	1,230	1,979
In nickel-base alloys	1,272	2,623
In copper-base alloys	7,400	7,032
In aluminum-base alloys	980	1,318
In ferrous and high-temperature alloys[1]	10,015	4,205
In chemical compounds	33	723
Total	20,930	17,880

[1] Includes only nonferrous nickel scrap added to ferrous high-temperature alloys.

CONSUMPTION AND USES

Pure unwrought nickel increased its share of the total U.S. nickel market in 1975 at the expense of ferronickel and nickel oxide. Pure nickel accounted for 68% of the total nickel consumed in 1975 compared with 59% in 1974 and 62% in 1973. Most of the pure nickel was consumed in the production of nickel wrought products and nickel alloys and electroplating. Ferronickel accounted for 17% of the total nickel consumed in 1975 compared with 22% in 1974 and 18% in 1973. Principal consumption of ferronickel was in stainless and alloy steels.

The pattern of nickel consumption in 1975 was as follows: 26% in stainless and heat resisting steel; 25% in other nickel and nickel alloys; 13% in electroplating; 14% in alloy steel; and 6% in nickel-copper and copper-nickel alloys.

A combination of reduced nickel consumption, a continued high level of imports, and the possibility of future price increases resulted in consumer stocks of nickel reaching high levels in 1975. Consumer-held stocks of nickel were being worked off at yearend. The surplus supply situation was compounded by the simultaneous startup of Marinduque Mining & Industrial Corp.'s mine and smelter in the Philippines, Freeport Queensland Nickel Inc.'s mine and treatment plant in Australia, AMAX Nickel Division's rehabilitated refinery in Louisiana, and production from a mine and smelter located in Botswana.

Table 4.—Stocks and consumption of new and old nickel scrap in the United States in 1975

Chemicals (catalysts, ceramics, plating salts and other chemical uses)	5	2	2	3
Total reported by companies canvassed and estimated	29,157	48,525	1,475	4,960

PRICES

The producer's price for electrolytic nickel was increased by INCO on August 29 from $2.01 per pound to $2.20 per pound. Nevertheless, INCO extended price protection at the old price of $2.01 per pound to all prior nickel customers until December 1.

The price of domestically produced ferronickel was increased on September 16 from $1.97 per pound of contained nickel to $2.16 per pound of contained nickel. Société Métallurgique Le Nickel increased the price of its nickel products on September 9. The new prices were as follows: FN4, $2.20 per pound of nickel content; FN3, $2.25 per pound of nickel content; FN1, $2.29 per pound of nickel content; FNC, $2.23 per pound of nickel content; and nickel rondelles, $2.26 per pound.

FOREIGN TRADE

The gross weight of U.S. exports of nickel, nickel alloys, and nickel catalysts (excluding scrap) was 4% less in 1975 than that exported in 1974. Exports of unwrought nickel in 1975 increased 110% over those exported in 1974.

Canada continued to be the principal supplier of nickel to the United States in 1975 and accounted for 62% of the total nickel imports for consumption. Canada's portion of the total imports was 4% higher than in 1974. New Caledonia replaced Norway as the second most important source of imported nickel and accounted for 11% of the total nickel imported. Norway, the Dominican Republic, and Australia completed the top five countries supplying nickel to the United States. These five countries accounted for 88% of the total nickel imported in 1975. Imports of ferronickel decreased from 15% of total primary nickel imports in 1974 to 13% in 1975, while unwrought nickel increased from 62% in 1974 to 67% in 1975. The total of all forms of primary nickel imported for consumption in 1975 was 27% less than that imported in 1974.

[3] Less than ½ unit.

WORLD REVIEW

Australia.—Near yearend 1975, the Australian Government appeared to be softening its stand on foreign equity participation as it related to control of the mining industry in that country. The basic requirement was that foreign investment in the development of raw materials be limited to no more than 50% of the equity and that no more than 50% of the votes on the board of directors be foreign. The Prime Minister stated that the regulations should serve as guidelines instead of constituting inflexible rules. He also emphasized that each investment proposal would be considered on a case-by-case basis. Also, it would not be mandatory for foreign exploration companies to seek Australian participation at the outset of initial exploration programs.[3]

Western Mining Corp., Ltd., had a capacity to produce 42,000 tons of nickel per year in 1975. Expansion plans underway in 1975 would raise this capacity to 71,500 tons and make Western Mining about equal to Société Métallurgique Le Nickel's (SLN) New Caledonian operation and approach the capacity of Falco. The cost of the expansion was reported to be $36 million. At the Kalgoorie smelter new

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Refined nickel plus nickel content of ferronickel produced from concentrates unless otherwise specified.

[2] In addition to the countries listed, North Korea is believed to produce metallic nickel and/or ferronickel, but information is inadequate to make reliable estimates of output levels.

[3] Includes nickel content of nickel oxide and nickel fonte in addition to metallic nickel and ferronickel.

[4] Nickel content of ferronickel only (no refined nickel is produced).

[5] Nickel-cobalt content of ferronickel and matte produced.

[6] Individual figures for byproduct metal refinery and recovery from domestic ore are withheld as company confidential information.

capacity was completed during 1975 and the installation of additional equipment to handle 385,800 tons of concentrate per year was nearing completion. Modifications and new equipment added to the Kwinana refinery during the year, increased annual production to about 26,500 tons. Western Mining continued exploration around the Kambalda and St. Ives area and reported reserves of 27 million tons of ore grading 3.23% nickel. Production of concentrate from a joint venture at Windarra began in September 1974 and Western Mining received 3,614 tons of nickel plus copper as its share of the venture during 1974–75. Ore reserves at Mount Windarra and South Windarra reportedly were 8,100,000 tons grading 1.88% nickel. The company also purchased ore and concentrate from the Nepean mine jointly owned by Metals Exploration N.L. and Freeport and from the Scotia and Carr Boyd Rocks mines now wholly-owned by Great Boulder Mines Ltd. Production from the Carr Boyd Rocks mine was suspended at midyear 1975 because the mine was unprofitable. Production from the Scotia mine was hampered by a ground collapse in July 1974. Selcast Exploration Ltd. continued to supply nickel ore to Western Mining from its mine at Spargoville. Annual production of nickel from concentrate was reported to be 4,000 tons.

The Greenvale nickeliferous laterite project in Queensland was plagued with early startup troubles. The principal problem areas were in the crushing and grinding section, the feed system to the furnace, and in the oxide and sulfide product processing sections. The roasting furnaces and the leaching and carbonate extraction sections were performing satisfactorily. Floods, strikes, inflation, and currency changes have helped to increase the original 1971 estimated cost of the project from $250 million to $382 million. As a result of these increased costs, the project ran into financial troubles early in 1975. About midyear outside money lenders, already involved in the project, and the Queensland State Government agreed to assist Metals Exploration N.L. in obtaining the needed financial backing. Metals Exploration was to supply about $1.3

million of the total amount required with the remainder supplied by lenders in proportion to their other loans on the project. The Queensland Government was to guarantee the loans. Production during September averaged 80% of capacity (46 million pounds of nickel per year). Full capacity was expected to be reached at Greenvale and the Yabulu treatment plant by 1977.

A decision on whether to proceed with the Agnew nickel project in Western Australia was deferred by Western Selcast (Pty.), Ltd., and Mount Isa Mines, Ltd. (MIM). Reasons cited by company officials were inflation and increased operating costs in relation to the international price of nickel. Further, the financial viability of the project had not been established. Nevertheless, the situation was to be kept under constant review and design work was continued. The Agnew sulfide deposit was estimated to contain 45 million tons of ore averaging slightly more than 2% nickel with a cutoff grade of 1%.

A major new nickel venture was shaping up in Western Australia at yearend. The Forrestania project called for the development of the Digger Rocks nickel deposit (30%-owned by Endeavor Oil Co. NL) and the Cosmic Boy deposit (owned by AMAX Inc.). AMAX would act as manager of both deposits. Reserves of contained nickel were reported to be 137 million pounds at Digger Rocks and 240 million pounds at Cosmic Boy. The government had committed itself to permit the venture to proceed with only 30% equity participation by Australian companies. Western Mining was mentioned as a possible partner in the venture. Provided the program could get started early in 1976, production from the Digger Rocks deposit might be possible for mid-1979 and underground production from the Cosmic Boy deposit 19 months later. The Forrestania operation would be located 250 miles southeast of Perth and 150 miles southwest of Kalgoorlie.

Botswana.—Officials of Botswana Roan Selection Trust, Ltd. (BRST), stated that continuing technical problems associated with poor recoveries, lack of equipment, and the shutdown of the flash furnace earlier in the year for repairs resulted in a disappointingly low matte production of 7,103 tons, only 30% of designed capacity. Officials estimated that the rated capacity of about 23,700 tons of matte per year would be achieved in 1976. A pay dispute among African workers resulted in a strike at Pikwe on July 29, 1975. Production was resumed after police were called to disperse the crowds. Production loss from the strike amounted to about 4 days. Major damage to the smelter was averted by the police response. Had smelter technicians been delayed from attending the furnaces much longer, the smelter would have been put out of service for at least 6 months as a result of matte solidification.

Brazil.—Brazil currently has two nickel mines located in Minas Gerais producing about 220,000 tons of ore per year containing nearly 3,000 tons of nickel. The ore is smelted to ferronickel (containing 24% nickel).

Cia. Niquel Tocantins had reserves estimated at 22 million tons of ore grading 1.7% nickel at Niquelandia, Goiás. Empresa de Desenvolvimento de Recursos Minerais (Codemin), had ore reserves of 16.5 million tons grading 1.4% nickel also in Goiás.

The most advanced new nickel project in Brazil was that proposed by Baminco Mineração e Sidérurgia S.A. (BAMINCO) for development in the State of Goiás. Reserves were estimated at 44 million tons of ore with an average grade of over 1.9% nickel and a cutoff grade of 1.2%. Plans called for erection of a smelter near the deposit to produce about 50 million pounds of nickel per year as ferronickel. Implementation of the project is estimated at 38 months after a decision is made to proceed. An economic feasibility study was underway during 1975.

Canada.—In 1975 the value of nickel production exceeded copper as the most valuable Canadian metal produced (539.7 million pounds of nickel valued at C$1,110 million compared with 1,600 million pounds of copper valued at C$1,020 million). Canada continued to dominate as the leading producer of nickel in the world and accounted for 30% of the total world mine production. Nickel production was reported as 269,826 tons of contained metal, a 9% decrease from that produced in 1974. The principal producers of nickel in Canada remained INCO, Falco, and Sherritt Gordon Mines, Ltd.

INCO mined a total of 21.2 million tons of ore having an average nickel content of 1.40% in 1975 compared with 22 million tons having an average nickel content of 1.37% in 1974. Nickel production by INCO in 1975 was reported to be 460 million pounds compared with 510 million pounds in 1974. Principal reasons cited for reduced production were short strikes at the Sudbury and Shebandowan, Ontario, operations. INCO reported proven reserves in Canada of 415 million tons, containing 6.7 million tons of nickel and 4.3 million tons of copper. The company operated 16 mines during 1975, 13 in Ontario and 3 in Manitoba. INCO began work on developing a new mine in the Sudbury area known as Levack East. Production was to begin in 1984. Redevelopment work at the Victoria mine halted production at that mine in December 1975, production was scheduled to resume late in 1976.

The Kirkwood ore bodies were expected to become depleted during the first quarter of 1976 and would be closed. Work was continued on deepening the Birchtree mine and on underground exploration at the Pipe mine, both in Manitoba. INCO demonstrated a desire to diversify its activities by the acquisition of the Electric Storage Battery Co. (ESB); Daniel Doncaster & Sons Ltd. of Sheffield, United Kingdom (producers of forged and machined products for gas turbines); and its announced intentions to construct in the Sudbury district of Canada a $29 million direct rolling mill utilizing metal powders. The company also announced in April 1975 its participation in a multinational joint venture to mine manganese nodules from the ocean floor. Other members of the consortium were Deep Ocean Mining Co. Ltd. (DOMCO), representing Japanese companies; Metallgesellschaft AG, Preussag AG, Rheinische Braunkohlenwerke AG, and Salzgitter AG from West Germany; and a U.S. company, SEDCO, Inc., of Dallas. The members were conducting feasibility studies during 1975.

Falco and Sherritt Gordon remained the number 2 and 3 producers, respectively, of nickel in Canada in 1975. Falco's Sudbury operations were shut down for 73 days in 1975 as production and maintenance workers went on strike. The company was forced to cutback production at its mines and plants by 30% after the strike because of reduced world demand for nickel. Output at the Falco refinery in Norway was curtailed in August as a result of the strike and remained at about two-thirds of normal capacity through yearend. Also, the East, Onaping, and Longvack South mines; the Fecunis mill; and one of two blast furnaces at the smelter were shut down and placed on standby status. Major capital projects at Sudbury (excluding development of the Lockerby mine) were suspended. Principal among these projects was the $95 million environmental improvement program for the smelter. Much construction work has been completed on the project. As a result of these actions, Falco reported that deliveries of refined nickel in 1975 totaled 61.5 million pounds compared with 89.5 million pounds in 1974. At yearend the Ontario Government deferred for 5 years its ruling that would have disallowed the deduction from taxes of the cost of processing minerals outside of Canada. Had the ruling been imposed, it would have cost Falco $8 million for 9 months of 1974 (levy's effective date was originally April 9, 1974).

Falco conducted research and development work in 1975 on mineral dressing techniques in order to increase metal recoveries at its Sudbury operations and to assist Sturgeon Lake Mines Ltd. in improving metal recoveries. A new method for hydraulically hoisting lump ore at the Onaping mine was deferred as a result of the mine being shut down. Ore reserves at yearend 1975 were reported as 89.1 million tons containing 1,279,000 tons of nickel. This was 1,479,000 tons of ore below the yearend 1974 quantity, the result of mining 3,230,000 tons of ore during the year.

Sherritt Gordon experienced a shortage of feed material during the second quarter of 1975 that restricted nickel production at its Fort Saskatchewan plant. Reportedly, the company shut down the refinery for 6 weeks (from mid-June to the end of July) for maintenance. The company expected to achieve closer-to-optimum operating levels during the final 5 months of 1975. The Lynn Lake mill improved its previous operations during the second quarter of 1975.

Production, as measured by sales and deliveries and reported by the three principal Canadian producers in 1975, was as follows:

Company	Type of operation	Thousand pounds
The International Nickel Co. of Canada, Ltd	Delivery	851,120
Falconbridge Nickel Mines, Ltd	do	61,524
Sherritt Gordon Mines, Ltd	Sales	20,036

Union Minière Explorations and Mining Corp. Ltd. was developing a new copper-nickel mine at Pickle Lake in Northwestern Ontario. Reportedly the mine will be a combination of open pit and underground operations and has sufficient ore reserves to last 20 years. To date, preliminary mine design, as well as geotechnical and environmental studies, have been completed.

Colombia.—Early in 1975 Hanna Mining Co. querried several Japanese stainless steel producers on the possibility of taking part in a joint venture to develop its nickel deposits at Cerro Matoso. A feasibility study was to be completed in 1975 on the project. Reportedly, a pilot plant was being constructed and preliminary financing inquiries were made both in the United States and Europe. Preliminary plans called for construction of a ferronickel plant with an annual capacity of 23,000 tons of nickel.

Cuba.—Reportedly, Soviet technicians were working on the nickel facility at Nicaro during 1975. The project was undertaken to construct new shops, modernize a railroad, and renovate the plant which was built during World War II. Expansions at Nicaro and Moa Bay will increase Cuba's nickel capacity by nearly 11,000 tons per year.

Dominican Republic.—Falconbridge Dominicana, C. por A., mined 2.3 million dry tons of lateritic ore in 1975. Deliveries of ferronickel in 1975 were reported as 52,329,000 pounds (contained nickel) compared with 68,709,000 pounds in 1974. Ore reserves were stated as 64 million dry tons grading 1.58% nickel at yearend. The company continued exploration within the concession area; the results were being evaluated at yearend.

France.—The French Government set aside about $56.5 million for developing a raw materials stockpile. The major portion of the money was destined for purchases of copper and nickel in 1975. The purpose of the stockpile was to protect industrial consumers against sudden fluctuations in metal prices. Metal stocks were stored throughout the country with consideration going to locations near specific metal consumers. The nickel stockpile was being managed by the nickel producer at Le Havre and was set up to assist SLN of New Caledonia through periods of poor marketing conditions. The nickel stockpile was to be about 10,000 tons of nickel metal and cover an acquisition period of 5 years.

Guatemala.—Exploraciones y Explotaciones Mineras Izabal, SA (Exmibal), reported that construction of facilities for its lateritic nickel project near Lake Izabal in eastern Guatemala neared the halfway mark at yearend. During 1975 construction and operating personnel amounting to 2,000 were employed at the site. The project was expected to begin operations in 1977 with a capacity of 28 million pounds of nickel per year in nickel matte. The cost of the project was revised in 1975 to $224 million.

Greece.—Expansion of the Société Minière et Métallurgique de Larymna S.A. (LARCO) ferronickel plant from 18,000 tons of nickel per year to 36,000 tons was awaiting government approval at yearend. LARCO processes 700,000 tons of ore per year into ferronickel containing 27% nickel. Ore reserves in the Larymna area were reported to be 100 million tons. A second proposal also was being considered by the government to combine steel production with the nickel output. Costs of the two projects were estimated to be $75 million and $220 million, respectively.

Indonesia.—INCO, the major share holder in P.T. International Nickel Indonesia, stated that construction of facilities for the first stage of its lateritic nickel operation was 60% complete at the end of 1975. During the year, nearly 6,500 construction and operating personnel were employed. The first stage, designed to produce 35 million pounds of nickel per year in matte, was expected to be operational by the latter half of 1976. In November 1975 the estimated cost of the project was escalated upward to $820 million. An agreement was reached during the year between INCO and the Indonesian Government for the construction and operation of a 110-megawatt hydroelectric plant on the Larona River. A major portion of the electricity will supply power to the nickel operation when it is expanded to 100 million pounds per year of nickel in 1978. Site preparation for the dam was started during the year.

P. N. Aneka Tambang (ANEKA) held discussions with four Japanese ferronickel producers during 1975 about the possible future supply of ferronickel to Japan. A ferronickel plant was to be completed in November 1975 and ferronickel was to begin being produced in April 1976 at a rate of 385 tons per month. The Japanese companies have contracted to purchase the output for 10 years. ANEKA was Indonesia's only producer of nickel ore in 1975. Near midyear 1975, ANEKA agreed to reduce ore shipments to Japan by about 30% for the fiscal year (April 1975 to March 1976). The shipments were to be reduced from 750,000 to 600,000 tons. The exported ores graded 2.4% nickel plus cobalt and 27% moisture.

Plans for the P.T. Pacific Nikkel Indonesia project were stalled near midyear as a result of cost escalation. Recent findings by Bechtel Corp. in a feasibility study increased the cost of the 100 million-pound-per-year operation to $700 million. The Gag Island project has been under study and development since 1968.

The Indonesian Nickel Development Co. (INDECO), a partnership of Japanese steel and trading firms, continued to explore for nickeliferous laterites. Attention was centered on the ores of Gebe Island near Halmahera. A feasibility report on the project was to be completed in September 1975.

Japan.—Japanese ferronickel producers, faced with large surpluses of nickel due to slack demand, requested Indonesian and New Caledonian ore exporters to reduce their shipments for the year. In order to reduce stocks of nickel, Japan's Ministry of International Trade and Industry (MITI) resumed the issuing of export licenses for nickel and nickel alloys. The new ceiling of up to 2,000 tons (total exports) was to remain in effect until March 1976. MITI officials stated that this ceiling would be increased if conditions required it.

Pacific Metals Co. of Japan attempted to interest five other Japanese firms in becoming joint owners in a new 44,000-ton-per-year ferronickel smelter in Niigata Prefecture. The first phase of the project (18,000 tons) was scheduled to begin early in 1976. Annual capacity was to be increased to 27,500 tons and finally to 44,000 tons in later years. First phase costs were estimated at $66.7 million. In a separate action, Shimura Kako Co. Ltd. (30% owned by INCO) was considering a plan to give INCO a larger share in the nickel refining company. Reportedly the company had been operating at a loss.

New Caledonia.—Production of nickel ore in New Caledonia in 1975 was 4% less than that produced in 1974 and totaled 7.4 million tons. Nickel smelter production increased 5% in 1975 over that of 1974 and totaled 78,338 tons. Ferronickel production increased nearly 9% and totaled 58,204 tons, but matte production decreased 3% from that of 1974. Exports of nickel ore to Japan decreased 26% in 1975 when compared with exports in 1974 and reflected Japanese requests for reductions in New Caledonian exports. Exported ore averaged 2.46% nickel plus cobalt.

Much discussion occurred during 1975 regarding the development of nickel deposits in the northern part of New Caledonia (Poum and Tiebaghi deposits). Compagnie Française d'Entreprises Minières, Métallurgiques et d'Investissements (COFREMMI) had its mining rights to New Caledonian nickel deposits suspended early in 1975. AMAX appeared interested in becoming a partner in developing these deposits, but the French Government apparently was holding up a decision on development until additional French interests in the project could be found. By midyear, the Minister of Overseas Departments and Territories announced that the government would participate in the project up to a possible 51% if no other French interest could be found. At yearend, AMAX reportedly was waiting for the French Government to make the next move in putting together a team to develop the project.

SLN officials announced plans to begin a $230 million expansion of its New Caledonian production facilities. The expansion would increase capacity of the Doniambo smelter from 70,000 to 90,000 tons per year by 1979.

Early in 1975 INCO won a tentative 2-

year delay from the French Government in which to make its decision about developing the Goro deposit in southern New Caledonia. The French Government divided the Goro deposit in half with INCO getting the western portion (with a 2-year delay) and Société Nationale des Pétroles d'Aquitaine (SNPA) getting the eastern portion. As a result of the division INCO was expected to offer a scaled-down development plan.

The long-awaited New Caledonian tax reform was approved in 1975. The new tax law will substitute a 50% tax on profits from the off-island sale of ferronickel and matte for the current 11% value added tax on all nickel exports. Reportedly, France will provide, for a period of more than 5 years, any revenue shortfall in that portion of the New Caledonian budget normally obtained from nickel taxes. Revenues from nickel have accounted for about 25% of the island's budget in recent years. Nickel processors would be required to pay a minimum guaranteed revenue equal to a 3% ad valorem tax on exported products. This export tax would be paid in full if processors recorded zero profits or deficits, and as a differential for any shortfall in profit taxes below the minimum guaranteed revenue.

Philippines.—Marinduque Mining & Industrial Corp. operated its new nickel facilities on Nonoc Island at about 27% of rated annual capacity (75 million pounds per year of nickel briquets and powder) during 1975. Operating capacity increased near yearend, 39% in November and 45% in December. Reportedly, the company produced 6.2 million pounds of pure nickel in the first half of 1975. Delays were encountered during the year as sections of the plant were redesigned. The company was considering building a hydroelectric powerplant that was expected to cut fuel oil requirements in half. The hydroelectric project would require up to 3 years to complete, once financing was found. At yearend, Marinduque was attempting to reschedule a portion of the nickel project's indebtedness. Officials hoped to reschedule $20.4 million due in 1976 so as to be payable over a 3-year period in quarterly installments beginning in January 1978. An additional $32 million due in January 1979, hopefully would be rescheduled over a 3-year period in quarterly payments beginning in January 1979.

The Japanese Government announced that an $18 million loan had been granted for the development of nickel ore reserves in the Philippines. The development company would be Rio Tuba Nickel Mining Corp. in which Pacific Metals Co. of Japan owned 40%. The company would produce 386,000 tons of ore the first year and 550,000 tons each succeeding year for shipment to Japanese ferronickel smelters. Total reserves were estimated at 22 million tons grading 2.2% nickel.

Rhodesia, Southern.—Rhodesia's fourth major nickel producer began operations at the Shangani mine in October 1975. Two separate ore bodies exist at the Shangani deposit. The larger eastern ore body had been estimated at 17.6 million tons grading 0.92% nickel and 0.12% copper. Initially the deposit will be mined at an annual rate of 992,000 tons of ore delivered to the concentrator for a period of 7 years, after which ore will be supplied from an underground mine. The concentrate will be shipped by rail some 200 miles to Rhodesian Nickel Corp. Ltd.'s (Rhonickel) Bindura smelter. The smelter recently underwent expansion in order to handle the Shangani concentrates as well as Rhonickel's output from the small Epoch mine. The smelter was originally designed to process concentrates from Rhonickel's Bindura and Madziwa mines. The Epoch mine is being developed at a cost of $11.9 million and was expected to be operational early in 1976. Reserves at Epoch were reported to be 2.75 million tons of ore grading 0.75% nickel. Mining was expected to last for about 8 years. Reportedly, Rio Tinto (Rhodesia) Ltd.'s Perseverence nickel mine was shut down in 1975 pending a metallurgical solution to the ore's high-arsenic content. The smelter feed ratio of Perseverence to Empress ore was adjusted to compensate for the high arsenic content of the Perseverence ore. Stockpiled ore at the Perseverence mine was sufficient to maintain smelter production for about a year, after which Rio Tinto will resume mining the Perseverence ore.

Yugoslavia.—Feni Kombinat of Yugoslavia reportedly began work on its new mine site at Rzanovo, 24 miles southwest of Kavadarci in November 1974. The Feni reserves are in three main ore bodies: The Rzanovo, estimated to contain 38 million tons of nickeliferous ore; the Bojančište, just north of Rzanovo, estimated at 400,000 tons which will be mined by open pit techniques; and the Studena Voda (an extension of the Rzanovo deposit), estimated to contain 200,000 tons but had not been fully explored. The ore was reported to assay 17.1% to 46% iron; 0.6% to 1.4% nickel; 0.02% to 0.14% cobalt; 0.9% to 2.2% chromium; 19% to 37% silicon dioxide; and 7% to 17% magnesium dioxide. The ore was to be smelted to a crude FN4 ferronickel containing about 19% nickel. Additional refining will remove iron and minor impurities and upgrade the product to FN1 ferronickel containing 25% nickel. If it is required, a 45% nickel content product would be produced. Pigs weighing about 66 pounds will be cast. Arthur G. McKee & Co. of Cleveland, Ohio, signed an engineering contract on May 16 with Feni. McKee will provide basic engineering and help coordinate construction of the complex.

TECHNOLOGY

Bureau of Mines scientists reported research results on recovering nickel and cobalt from low-grade domestic laterites.[4] The Bureau's process involves selective reduction of laterite ore with carbon monoxide at temperatures ranging from 350° to 600° C. Materials containing more than 5% magnesia required additions of pyrite or postreduction heat treatments to achieve satisfactory nickel and cobalt extractions for this range of reduction temperatures. The reduced material was leached in multistages at ambient temperature and pressure in the presence of oxygen, ammonium sulfate, and ammonium hydroxide. Extractions were about 90% and 85% of the contained nickel and cobalt, respectively. Bureau of Mines researchers also reported on the copper-nickel mineralization of the Duluth Gabbro complex. A microscopic study was performed to determine the mineralogy and paragenesis of the ore minerals. Major sulfide minerals were chalcopyrite, cubanite , pyrrhotite, troilite, and pentlandite.[5] Other published reports by the Bureau of Mines described the thermodynamic properties of Al–Ni alloys containing 0.54 to 30.04 atomic-percent nickel.[6] The chlorination kinetics of selected metal sulfides, including nickel sulfide, were described in a separate report.[7]

Scientists from four Bureau of Mines metallurgy research centers continued to carry out nickel related research. Research programs included the extraction of nickel and cobalt from domestic oxide ores and nickel-copper sulfide ores in an attempt to optimize operating parameters. Other areas being studied were the recovery of cobalt and nickel as byproducts of concentrating and smelting Missouri lead ores, development of a process for economically recovering manganese and other metals from calcareous Atlantic Ocean nodules from the Blake Plateau and from the Pacific Ocean, and the development of an environmentally acceptable method for treating copper and nickel sulfide ores associated with the Duluth Gabbro complex.

A solvent extraction process for the separation of cobalt from nickel was described in a paper by researchers from the Canadian Government's Mines and Resources Department in Ottawa.[8] After the cobalt and nickel are leached from ores, residues, alloys, or other materials with conventional inorganic acids, unwanted metals are removed. The remaining solution containing cobalt and nickel is treated with either sodium or ammonium salt of di(2-ethylhexyl) phosphoric acid which extracts most of the cobalt and a small amount of nickel. Cobalt is recovered from the solvent by acid stripping. In a somewhat related report, the researchers investigated the extraction and separation of copper, nickel, zinc, and cobalt from ammoniacal solutions using Kelex 100.[9]

A newly developed sealed nickel-hydrogen battery was announced which offers advantages over such batteries as nickel-cadmium, lead-acid, silver-zinc, and the regenerative H_2–O_2 fuel cell.[10] Advantages claimed for the new cell are that it is lightweight and has a longer life, higher energy, and increased power densities. Reportedly, over 5,000 high rate discharge-charge cycles were completed on small 1.5 ampere-hour cells with good voltage performance. NASA's Jet Propulsion Laboratory tested similar cells in high altitude, zero-G flights from the White Sands, N. M., testing grounds. Reportedly, the cells performed well under heavy discharge conditions. Studies indicated the possibility of 50% more charge-discharge cycles than are possible with nickel-cadmium cells. In a somewhat related development, nickel-zinc batteries were described that may eventually supplement, rather than replace conventional lead-acid batteries.[11] The Lewis Research Center in Cleveland, Ohio, was preparing to test these batteries in an electric vehicle (EV) used to deliver mail on the Center's property. Spokesman for the Center believed that the use of nickel-zinc batteries would give EVs a range of 80 to 100 miles compared with a range of 40 to 50 miles for lead-acid batteries before recharging is required. A new wrought aluminum-nickel alloy for high strength-high conductivity applications was developed.[12] These alloys contain from 0.06% to 6.1% (by weight) nickel and can be processed into wire as easily as aluminum. The wire possesses the desired characteristics of high strength-high electrical conductivity.

A new nickel-iron alloy (Niron) was developed by the Udylite Co., Division of Oxy Metal Industries Corp., Warren, Mich., as a substitute for nickel in electroplating.[13] The alloy gives the brilliance, leveling, durability, and speed of bright nickel plating with the economy of iron. The deposit was reported to be ductile, to have good corrosion resistance, and to accept a chromium deposit well. Use of the Niron process allows a deposit of an alloy containing 15% to 30% iron in place of one made entirely of nickel. Reportedly, economies result not only from reduced nickel consumption but also from the elimination of nickel chloride and the extension of the life of anode bags and filters. Officials of Corning Glass Works announced the development of a plating chemical recovery system for chrome and nickel that could possibly reduce consumption by 50% to 90%.[14] The unit was referred to as a climbing film evaporator.

Deep Ocean Minerals Association (DOMA) announced plans to build a new research vessel to be used to survey for deep sea manganese nodules.[15] The ship will be equipped with a radioactive (gamma ray) surveying system to measure nodule quality, an automatic route map preparation system to outline nodule distribution and quality, an ultrasonic system to permit high-precision surveying of ocean bottoms, and a system for collecting nodules from the deep ocean. Also under development, was a high-speed television system to permit picture taking of nodules while the ship is moving at high speeds.

A company official for Frankel Company, Inc., described how to make use of technology to identify and segregate expensive scrap for recycling.[16] The company processes lathe turnings, stamping trim, and other manufacturing scrap metals which a short time ago were considered worthless. The volume of scrap recycled at Frankel has reached 2 million pounds per year. Alloy scrap identified and processed included INCO alloys 718 and 901, Waspalloy, and Hastelloys. The firm relies on atomic absorption spectrophotometers, a direct reading X-ray fluorescence spectrometer, and an automatic carbon and sulfur determinator. The chips are sorted and identified, chopped, crushed or sheared, washed to remove soil, dried, screened, and boxed according to customer specifications.

were tested during 1975 as a possible substitute material for traditional titanium fan blades.[17] The leading edge has a damage resistant electro-deposited nickel-cobalt sheath. The U.S. Air Force was evaluating the new composite blades in actual flight tests in a F-111D fighter. The all composite third-stage blades were reported to be 40% lighter than conventional titanium blades. The composite blades were made from 4.2 mil silicon-carbide-coated boron filaments. Maximum use of the material in a jet engine could reduce the engines weight by 15% to 20% according to the Air Force project manager.

A new method has been developed for die casting of ferrous metals and nickel and cobalt alloys.[18] Principal difficulty in diecasting of these materials has been that die materials cannot withstand the casting metal's temperature. The GKN Group Technological Center at Wolverhampton, England, developed a Ferro-Di process which utilizes a titanium-zirconium-molybdenum insert in the die. The Massachusetts Institute of Technology, Department of Materials Science and Engineering, was researching a diecasting method in which conventional die materials were used but the molten metal was agitated into a slurry. This method effectively reduced the alloy temperature. The Ferro-Di process has been developed into a production reality for diecasting of numerous metals and alloys.

A new superalloy Pyromet CTX-1 was developed which has mechanical properties about equal to Alloy 718, but a mean coefficient of thermal expansion only about one-half of alloy 718.[19] The new alloy has no chromium in its composition but still retained its corrosion and oxidation resistance.

A high level of industrial activity was evident from the large number of patents issued during 1975. The patents covered a wide range from mining through extractive metallurgy (both pyrometallurgy and hydrometallurgy) to processing technology. The processes were directed toward the recovery of nickel from lateritic and sulfide ores and deep ocean manganese nodules. The significance of a developing technology for mining and processing deep ocean nodules was evident from the large number of patents issued on the subject during 1975.

Nitrogen

By Russell J. Foster[1]

Fixed nitrogen production of 13.6 million short tons and elemental nitrogen production of 9.2 million short tons were 4% and 7%, respectively, above 1974 output. Exports of contained nitrogen increased 20%, and imports rose 12%. As in 1974, the United States was a net importer of fixed nitrogen. Domestic consumption, including net imports of 102,000 tons, was essentially unchanged at 13.0 million tons of fixed nitrogen. Domestic consumption of elemental nitrogen was considered equal to production.

Table 1.—Salient nitrogen statistics
(Thousand short tons of contained nitrogen)

	1971	1972	1973	1974	1975[p]
United States:					
Production as ammonia	12,107	12,651	[r] 12,641	13,121	13,595
Production as elemental nitrogen[1]	6,087	7,011	8,263	8,585	9,180
Exports of nitrogen compounds[2]	999	1,310	1,506	999	1,194
Imports for consumption of nitrogen compounds[2]	907	947	[r] 967	1,154	1,296
Consumption[3]	11,903	12,333	[r] 12,708	13,046	13,019
World: Production[2]	45,357	47,398	[r] 51,500	53,400	52,300

[p] Preliminary. [r] Revised.

[1] Converted from reported volume (at 70°F and 1 atmosphere pressure) at 27,605 cubic feet per short ton.

[2] Estimated, excludes elemental nitrogen.

[3] Includes producers' stock change in synthetic anhydrous ammonia and coke oven ammonium compounds; excludes elemental nitrogen.

Legislation and Government Programs.—The Environmental Protection Agency began an investigation of nitrosamines as cancer-causing agents. These compounds are formed by the combination of amines and nitrates, some of which are found in water due to fertilizer and pesticide runoff.[2]

The Occupational Safety and Health Administration, proposed tougher controls on worker exposure to ammonia, including a ban on all worker contact with liquid ammonia. High exposure to ammonia can lead to acute lung congestion, followed by bronchitis or pneumonia with possible permanent lung damage and even death from concentrations of several thousand parts per million.[3]

Ammonium sulfate and mixed and blended fertilizers were included in the fertilizer manufacturing category when final effluent limitations guidelines for existing sources and standards of performance and pretreatment standards for new sources were established.[4] Twelve companies representing the major nitrogen fertilizer manufacturers joined in a petition for judicial review of the regulations for nitrogen fertilizers, including urea. Data and information received from industry contributed to the development of new urea regulations, which apply to plants that started prilled urea production after January 1, 1970, and to new sources. A further study will be undertaken for use in developing regulations for plants that began production before January 1, 1970, and for plants that do not prill urea product.[5]

DOMESTIC PRODUCTION

Domestic production of fixed nitrogen, as anhydrous ammonia, increased 4% over that of 1974 to nearly 13.6 million short tons. Elemental nitrogen production rose 7% to 9.2 million short tons.

Ammonia producers have succeeded in trimming their needs for natural gas in all production activities, according to an energy survey conducted by The Fertilizer Institute. The use of gas was down from 40,706 cubic feet per ton of ammonia produced in 1972 to 39,397 cubic feet per ton of ammonia in 1975, a drop of 3%. However, total Btu consumption rose slightly because less efficient sources of energy, such as fuel oil, were employed for some nonfeedstock use.[6]

The Council on Environmental Quality was urged to give heavy emphasis to the energy needs of the fertilizer industry in reporting to the President and Congress. The Fertilizer Institute pointed out that ammonia plants were forced to cut production by 356,000 tons in 1975 because of gas curtailments.[7]

Canada announced an increase in the price of natural gas exported to the United States. On August 1, the price was raised by 40% to $1.40 per 1,000 cubic feet and this was followed by a further increase in November to $1.60 per 1,000 cubic feet. The change in price affected U.S. ammonia producers in the Midwest and on the Pacific Coast.[8]

Farmland Industries Inc. announced its intention to build a 420,000-ton-per-year ammonia plant, due onstream in 1978, at Alexandria, La.[9] A 385,000-ton-per-year unit, due onstream by 1977–78, was already under construction by M. W. Kellogg Co., at Enid, Okla. Farmland's 200,000-ton-per-year urea-ammonium nitrate solutions facility at Dodge City, Kans., came onstream in January 1976. In addition, a 350,000-ton-per-year ammonium nitrate plant was planned for Enid, Okla.[10]

As Agrico Chemical Co. brought its Verdigris, Okla., fertilizer complex onstream, the company announced that ammonia capacity would be doubled to 850,000 tons per year. The $35 to $40 million expansion project was due for startup in 1977.[11] Agrico's 300,000-ton-per-year urea plant, constructed at Blytheville, Ark., came onstream in the spring of 1976.[12]

CF Industries, Inc., awarded Foster Wheeler Corp. and Hoechst-Uhde Corp. two contracts totaling $23.5 million to design and engineer fertilizer production facilities to include a 1,500-ton-per-day urea plant, a 520-ton-per-day nitric acid plant, a 660-ton-per-day ammonium nitrate plant, and a 500,000-ton-per-year 32% urea-ammonium nitrate solutions plant at Donaldsonville, La. Completion was slated for mid-1977.[13]

Air Products and Chemicals, Inc., announced plans to increase its New Orleans, La., ammonia production capacity by 250 tons per day. The new capacity was expected onstream in January 1976. Since a grassroots ammonia facility could take about 3 years to complete, Air Products bought certain idle ammonia production equipment to facilitate rapid construction.[14] The company also planned to construct a 300-ton-per-day nitrogen-oxygen-argon facility at La Salle, Ill.[15]

Monsanto Co. chose M. W. Kellogg to

design a 400,000-ton-per-year ammonia plant to expand its facilities at Luling, La. The plant, which would more than double the existing ammonia capacity at the site, was given a startup date of late 1976.[16] Allied Chemical International reopened a 100,000-ton-per-year ammonia plant at Southpoint, Ohio.[17]

Construction began in April on the $8.4 million expansion of Kaiser Aluminum & Chemical Corp.'s Savannah, Ga., nitrogen complex. Modifications will increase production capacity for ammonium nitrate solutions and urea.[18]

Beker Industries Corp. planned to build a 127,000-ton-per-year ammonia unit at Carlsbad, N. Mex. The ownership of the plant will be a joint venture with Texasgulf, Inc. Another larger plant, formerly operated by Northern Illinois Gas Co. was relocated and reactivated by Beker at the site, and a 160,000-ton-per-year urea plant came onstream there in late 1975.[19]

Mississippi Chemical Corp. announced plans to reactivate a portion of its original Yazoo City, Miss., ammonia plant and tie it into the existing 1,000-ton-per-day ammonia unit. Nearly 53,000 tons per year of additional ammonia production was expected when the $2.9 million project was completed in fall 1975. This construction was in addition to a $60 million, 2-year expansion already underway at the Yazoo City and Pascagoula, Miss., facilities.[20]

International Minerals & Chemical Corp. and Commercial Solvents Corp. scheduled a 1,150-ton-per-day ammonia fertilizer facility at Sterlington, La., with a projected opening in early 1977. Columbia Nitrogen Corp. announced plans to start production at a 1,500-ton-per-day ammonia plant in the Southeastern United States in early 1978. Collier Carbon & Chemical Corp. had in the engineering stage a 1,500-ton-per-day ammonia plant and a 1,200-ton-per-day granulated urea unit to be located at Kenai, Alaska.[21]

The Federal Power Commission denied USS Agri-Chemicals, Inc.'s priority for natural gas supplies to its 177,000-ton-per-year ammonia plant at Cherokee, Ala.[22] Shortages of natural gas at Vistron Corp.'s 510,000-ton-per-year ammonia plant at Lima, Ohio, forced the company to appeal to the Federal Power Commission. Early in 1975 gas supplies to the plant from Columbia Gas of Ohio were cut by 30% to 55%, and the company was notified that a 60% reduction was planned during the 5-month heating season starting November 1. The shortages have curtailed Vistron's ability to serve an estimated 66,000 farmers in seven Midwestern States.[23]

CONSUMPTION AND USES

U.S. consumption of fixed nitrogen remained at 13.0 million short tons in 1975. Consumption of elemental nitrogen is assumed to be equal to production, because no statistics are collected on stocks and international trade is negligible.

The principal use of fixed nitrogen was in fertilizers, which consumed approximately three-fourths of production.[24] Explosives, resins, fibers, plastics, and animal feeds were among the other uses. The two major uses of elemental nitrogen were as a gas to exclude or purge air from such industrial processes as steelmaking, electronics, chemical manufacture, and glassmaking, and as a liquid to provide low temperatures in food processing and scientific applications. These cryogenic processes were estimated at 18% of total use.

PRICES

Quoted prices of most major nitrogen compounds apparently remained stable during the year, after approximately doubling during 1974. Actual prices paid by American farmers for nitrogenous fertilizers reached their highest levels during the spring of 1975. Throughout the rest of the year, however, prices exhibited a steady decline, and by yearend, prices at the farm level had decreased about 20%. Contributing factors included increased production capacity without a corresponding increase in consumption, and the resulting higher inventories.

Table 5.—Price quotations for major nitrogen compounds in 1975
(Per short ton)

Compound	Jan. 1	Dec. 31
Ammonium nitrate, domestic, fertilizer-grade, 33.5% nitrogen, bulk, delivered	$91–$115	$91–$115
Ammonium sulfate, standard-grade, commercial, bulk, f.o.b. works	89	60
Anhydrous ammonia, fertilizer, wholesale, tanks, delivered east of Rockies, except east coast	190– 210	180– 190
Aqueous ammonia, 29.4% NH_3, anhydrous basis, tanks, freight equalized east of Rockies	165– 180	165– 180
Sodium nitrate, domestic, agricultural:		
Bulk, carlots, f.o.b. works	127	139
Bags, carlots, f.o.b. works	138	130
Sodium nitrate, imported, commercial:		
Bulk, carlots, f.o.b. Atlantic and Gulf warehouses	132	130
100-pound bags, carlot, same basis	143	141
Urea:		
Industrial, 46% nitrogen, bulk, 50-ton carlots, delivered East	160– 175	160– 175
Agricultural, 46% nitrogen, bulk, same basis	160– 175	160– 175
Agricultural, 45% nitrogen, bulk, 50-ton carlots, delivered East	160– 175	160– 175
Diammonium phosphate, fertilizer grade, 18–46–0, bulk, carlots, f.o.b. Florida works	145– 165	135

Source: Chemical Marketing Reporter.

FOREIGN TRADE

Exports of contained nitrogen increased by 20% in 1975. Exports in almost all categories were up, the exceptions being anhydrous ammonia and mixed chemical fertilizers. Exports over the period 1973–74 had declined 34%. Total imports also rose 12% in 1975. Since imports in nearly all categories were down from 1974, the overall increase was due to a sizeable increase in anhydrous ammonia imports. In 1975, as in 1974, the United States was a net importer of fixed nitrogen, in contrast to the previous decade. Fixed nitrogen imports in the period 1966–75 have increased steadily, while exports have shown a lesser, more cyclic, growth trend.

[e] Estimate. [r] Revised.

[1] Less than ½ unit.

[2] Effective January 1, 1975; formerly part of ammonium phosphates.

WORLD REVIEW

Abu Dhabi.—Two plants for the manufacture of ammonia and urea were planned by the Abu Dhabi Government. Most of the production was slated for export to reduce the country's dependence on the oil market for revenue.[25]

Algeria.—The French affiliate of M. W. Kellogg Co. contracted with Sonatrach for a 1,100-ton-per-day ammonia plant to be built at Annaba. The new plant will be near an existing phosphate fertilizer complex. The ammonia, to be produced from natural gas, will be primarily for use in Algeria.[26]

Australia.—Western Mining Corp., Australia's largest nickel producer, was establishing its own ammonia plant with a capacity of 55,000 tons per year at Kwinana. The facility was purchased from Consolidated Fertilizers Ltd. in Queensland, then dismantled and shipped by rail to Kwinana. The company was able to buy the plant at a much lower price than it would now cost to build one, and the plant gives the company more operational independence.[27]

Bangladesh.—Ashuganj Fertilizer and Chemical Co. Ltd. announced plans to construct an ammonia-urea plant at Ashugani. The plant will produce 1,760 tons per day of urea and 1,045 tons per day of ammonia using natural gas feedstock. The International Development Association will supply part of the finance.[28]

Belgium.—Ste. Carbochimique, S.A., planned to reactivate a 71,500-ton-per-year urea plant at Willebroek by 1976, to coincide with the scheduled completion of a 363,000-ton-per-year urea facility at Tertre.[29]

Canada.—Canadian Kellogg Ltd. was constructing a 396,000-ton-per-year ammonia plant and a 495,000-ton-per-year urea unit for Canadian Fertilizers Ltd., at Medicine Hat, Alberta. The Government of Alberta approved the company's proposed construction of a second ammonia plant of similar size.[30]

The Alberta Energy Resources Conservation Board approved proposals for two more ammonia plants. Alberta Ammonia Ltd. planned to construct a 616,000-ton-per-year facility at Raymond. The bulk of its production will be piped to Farmland Industries, Inc., of the United States. The company also applied for permission to build a second ammonia unit of similar size. The other project was a joint venture by Pan Canadian Petroleum Ltd. and the Tyler Corp. of Texas for a 310,000-ton-per-year plant at Brooks. Most of this plant's production was intended for export to the United States also.[31] Beker Industries Corp. reopened a renovated 179,000-ton-per-year ammonia plant at Sarnia, Ontario.[32]

China, People's Republic of.—The People's Republic of China produced an estimated 3 to 4 million tons of contained nitrogen in 1975. Thirteen large nitrogen-fertilizer plants have been contracted for or are presently under construction. In addition, there is a program to build numerous small plants. These facilities could push nitrogen-fertilizer production to 9 to 11 million tons of contained nitrogen by 1980.[33]

Cuba.—A considerable expansion was underway in Cuban ammonia and nitrogen fertilizer capacity. Unión Explosivos Rio Tinto, S.A. Spain's largest chemical manufacturer, finalized a contract to construct in Cuba a 1,100-ton-per-day ammonia plant with downstream urea and complex fertilizer units at an estimated cost of $120 million. In addition, the U.S.S.R. was assisting in the construction of ammonia, urea, ammonium nitrate, and nitric acid production facilities, which were scheduled for completion in 1976 at Nuevitas.[34]

Egypt.—Foster Wheeler Italiana was awarded a contract to build a 1,320-ton-per-day ammonia plant and a 1,900-ton-per-day urea plant at Talkhā. Both were scheduled to come on stream in 1978.[35]

[35] Page 21 of first work cited in footnote 12.

El Salvador.—A 163,000-ton-per-year ammonium sulfate plant was brought onstream at the port of Acajutla.[36]

France.—French chemical companies launched a major investment program in ammonia production to meet France's growing needs. The Industry Minister authorized construction of five units, which would increase capacity by more than 1 million tons, for a total capacity of nearly 4 million tons per year. Cie. Française de l'Azote scheduled a 1,100-ton-per-day plant at Bordeaux; Sociétè Chemique des Charbonnages (CdF Chimie), Grand Paroisse, and Produits Chimiques Ugine Kuhlmann formed a consortium to build a 1,100-ton-per-day unit at Villiers-St. Paul; Rhone-Poulenc S.A. and CdF Chimie have planned a joint venture of 1,100 tons per day at Rouen; Ste. Gardinier announced a 660-ton-per-day facility at Montoir-de-Bretagne; Grande Paroisse proposed the expansion of its ammonia plant at Waziers by 165 tons per day. Since 1973, French ammonia consumption has exceeded production. Without expansion, imports could have reached 550,000 to 990,000 tons by 1977 and 1.1 to 1.9 million tons by 1980.[37] The Government guaranteed natural gas supplies but refused to make any commitment to increase French ammonia prices.

Germany, East.—A 495,000-ton-per-year ammonia plant, designed by M. W. Kellogg Co. and constructed by Toyo Engineering Corp., came onstream at Piesteritz in September.[38]

Germany, West.—Construction of a 1,700-ton-per-day ammonia plant and a 1,000-ton-per-day urea plant in the Brunsbuttel area was announced by Veba Chemie AG and the Danish firm Superfos A/S. Both units were expected onstream in 1978.[39]

Greece.—Aeval, S.A., operator of the Government-owned nitrogenous fertilizer plant at Ptolemaís, planned the establishment of a 1,320-ton-per-day anhydrous ammonia unit and awarded the British firm of Humphrey-Glasgow the contract for preparation of a feasibility study. The new unit was slated to use Ptolemaís lignite as raw material.[40]

Hungary.—Petfurdo Nitrogen Works commissioned a new ammonia plant at Várpalota. The plant, which was designed by M. W. Kellogg, has a capacity of 300,000 tons per year of ammonia. A connecting urea plant, with a capacity of 100,000 tons per year of contained nitrogen, was also placed onstream in 1975.[41]

India.—The Government of India accorded the highest priority for fertilizer production facilities in an effort to achieve increased production and improved utilization of existing capacity. Construction of a fertilizer plant at Phulpur for the production of 990 tons per day of ammonia and 1,650 tons of urea per day was approved. The unit will be owned and operated by the Indian Farmers Fertilizer Cooperative Ltd. (IFFCO) and will utilize heavy fuel oil as feedstock and coal for steam and power generation.[42] In addition, IFFCO brought a 430,000-ton-per-year urea plant onstream at Kolol.[43]

The second ammonia and urea units at Namrup were brought onstream with capacities of 218,000 and 363,000 tons per year, respectively. Feedstock was natural gas from upper Assam oilfields. The Barauni fertilizer plant, consisting of a 220,000-ton-per-year ammonia unit and a 363,000-ton-per-year urea facility, was expected to be onstream in December. The Gujarat State Fertilizers Co. Ltd. was slated to receive a loan from West Germany for construction of a 490,000-ton-per-year ammonia plant and a 580,000-ton-per-year urea unit. The construction of four coal-based ammonia plants located in Madhya Pradesh and at Korba, Talcher, and Ramagundan have been approved. The latter two, designed by Montedison, were under construction by the Fertilizer Corp. of India Ltd. and were due onstream in 1977–78. Capacities will be 327,000 tons per year of ammonia and 690,000 tons per year of urea.[44]

Construction of the Nagarjuna Fertilizers Ltd. facilities at Kakinada was due to begin. The plans encompassed a 330,000-ton-per-year ammonia unit together with urea and complex fertilizer facilities. The complex was due onstream in 1979. Southern Petrochemical Industries Corp. Ltd. brought a 578,000-ton-per-year urea plant onstream at Tuticorin in late June. The associated naphtha-based ammonia plant entered production earlier in the year. A 363,000-ton-per-year urea plant was under construction at the Sindri complex of the Fertilizer Corporation of India.[45]

Part of a $17 million World Bank loan was to be spent on converting the Neyveli Lignite Corp. Ltd.'s 103,000-ton-per-year ammonia plant to naphtha operation.[46] Maharashta Co-operative Chemicals & Fertilizers Ltd. signed an $8 million contract with Haldor Topsoe of Denmark for the construction of an integrated ammonia and ammonium chloride plant at Tarapur. The facility was due onstream in 1977–78.[47]

Indonesia.—Indonesia planned to increase nitrogen fertilizer capacity to about 1.6 million tons per year with the third expansion of the complex at Palembang. P. T. Pupuk Sriwidjaja (PUSRI), the Indonesian petrochemical company, named Kellogg Overseas Corp. as contractor for a new complex, PUSRI IV, which would consist of a 1,100-ton-per-day ammonia plant and a 1,900-ton-per-day urea unit. PUSRI's original 110,000-ton-per-year urea plant at Palembang was built in 1959. PUSRI II, the 1974 expansion of the facility, consisted of a 725-ton-per-day ammonia plant and a 1,265-ton-per-day urea facility. PUSRI III, scheduled for completion in 1977, will provide 1,100 tons per day of ammonia and 1,900 tons per day of urea capacity.[48]

Iraq.—The Mitsubishi Group gained a major fertilizer plant contract from the Iraqi Government's Ministry of Industry for the construction of a 550,000-ton-per-year ammonia plant and a urea unit with an output of over 1 million tons per year at Khor al-Zubair.[49]

Ireland.—Nitrigin Eireann Teoranta awarded Kellogg International Corp. a contract for a nitrogen fertilizer complex at Marino Point. The 1,485-ton-per-day ammonia plant, 1,100-ton-per-day urea plant, and associated off-site developments were scheduled for completion in early 1978.[50]

Japan.—Ube Industries Ltd. planned to increase the capacity of its ammonia plant at Ube City by 275 tons per day by year-end 1975. Mitsubishi Gas Chemical Co. Ltd. decided to construct an 880-ton-per-day ammonia unit at Niigata beginning in 1976.[51]

Kuwait.—Kuwait Petrochemical Industries Co. awarded a contract to S.A. Coppee-Rust N.V. of Belgium to increase capacity of a urea plant at Shuaiba from 645 to over 1,100 tons per day.[52]

Libya.—Discussions continued on the addition of further fertilizer plants to the Marsa el Brega complex. Plans included the construction of another 1,100-ton-per-day ammonia plant, due onstream in 1978, and a 2,970-ton-per-day urea plant.[53]

Malaysia.—An $800 million petrochemical complex, including a 495,000-ton-per-year urea plant, was planned by Petronas Malaysia.[54]

Mexico.—Guanos y Fertilizantes S.A. planned a new fertilizer plant at San Juan del Rio, to include a 330,000-ton-per-year ammonium sulfate facility.[55] A 1,650-ton-per-day ammonia plant was scheduled at Coatzacoalcos, and a 1,100-ton-per-day unit was slated to come onstream at Bajío in early 1977.[56]

Netherlands.—The 740,000-ton-per-year ammonia capacity of the Sluiskil works was scheduled for a 50% expansion. A new ammonia plant with a capacity of 485,000 tons per year was planned for Geleen.[57]

Nigeria.—The Nigerian Government announced a feasibility study for two ammonia-urea complexes at Warri and Port Harcourt. The plants would be designed to utilize natural gas and refinery tail gases, which are currently flared. There are no nitrogen fertilizer facilities presently in Nigeria.[58]

Pakistan.—Snamprogetti reached agreement with the National Fertilizer Corp. of Pakistan for the construction of a $193 million, 363,000-ton-per-year ammonia unit and a 633,000-ton-per-year urea plant at Mirpur Mathels. Haripur was named as the location for a fertilizer project originally announced for the Peshawar area. Capacities for the ammonia and urea plants were 187 and 330 tons per day, respectively.[59]

Peru.—On April 19, 1975, Petroperú inaugurated the Talara fertilizer complex, which was built by Toyo Engineering Corp. of Japan at a cost of $44.2 million. The facility will produce 300 tons of ammonia and 510 tons of urea daily.[60]

Romania.—The Romanian state corporation, Romchim, accepted delivery of a 1,100-ton-per-day ammonia plant designed by M. W. Kellogg Co. at Tirgu-Mures. It was the first of six Kellogg plants slated for Romania. The others are proposed for Turnu-Magurele in 1976, Craiova in late 1976 or 1977, Arad and a second unit at Tirgu-Mures in 1977, and Tecuci.[61] A massive fertilizer complex to be financed by the World Bank was scheduled for construction at Bacau. Several of the plants will be duplicates of existing Romanian operations, but the urea unit to be built by Coppee-Rust will have an increased capacity of 462,000 tons per year. The entire complex, which also includes a major power station, is due to be completed in mid-1978.[62]

Saudi Arabia.—Petromin, the Government's minerals company, planned the construction of three large-scale nitrogenous fertilizer export plants. Two of the projects, with the U.S. firm Agrico Chemical Co. and the Taiwan Fertilizer Co., were joint ventures, but the third was wholly owned by Petromin, although carried out in association with Britain's ICI.[63]

Senegal.—Fertisen S.A. announced plans to build a 36,000-ton-per-year ammonia plant and a 55,000-ton-per-year urea unit at M'Bao near Dakar. The facility was scheduled for completion in 1977.[64]

South Africa, Republic of.—African Explosives and Chemical Industries, Ltd., started up its Rand coal-based ammonia plant at Modderfontein. The 1,100-ton-per-day unit formed the major part of the nitrogen project there.[65] Construction of a 825-ton-per-day urea plant by Kellogg Continental B.V. was also nearing completion.[66] A new chemicals-from-coal complex, which included a 110,000-ton-per-year ammonia plant was scheduled for completion in the Transvaal by 1981.[67]

Spain.—Kellogg International Corp., London, in cooperation with Tecnicas Reunidas, was engineering the Sefanitro S.A. 1,090-ton-per-day ammonia plant, which was scheduled for completion at Bilbao in 1977. The naphtha-fed plant was being designed for conversion to gas feedstock when gas becomes available.[68] A 990-ton-per-day ammonia plant using naphtha feedstock was scheduled for startup at Huelva in late summer. A new urea plant was slated for completion by Toyo Engineering Corp. at the same site in 1976.[69]

Sri Lanka.—The Fertilizer Manufacturing Corp. has planned a $163 million fertilizer complex at Hapugaskanda, including a 165,000-ton-per-year ammonia unit and a 330,000-ton-per-year urea plant, due onstream in 1978.[70]

Syria.—On October 1, 1975, a contract was signed between Unichem and Creusot-Loire Enterprises of France for the installation of a refinery and nitrogen fertilizer complex at Homs. The Kellogg-designed-and-engineered ammonia plant will produce 1,100 tons per day, and the Heurtey Industries-engineered urea unit will generate 1,150 tons per day. Naphtha from the refinery will be used as feedstock.[71]

Taiwan.—Ammonia capacity at the Nankong plant of Taiwan Fertilizer Co. has been expanded to 66,000 tons per year. Kellogg Continental was awarded a contract for a 327,000-ton-per-year ammonia unit and a 218,000-ton-per-year urea plant, due for completion at yearend 1977.[72]

Trinidad and Tobago.—Kaiser Aluminum & Chemical Corp. agreed to build a $150 million fertilizer complex. In addition to 1,100 tons per day of ammonia, the plant would also produce liquid urea, nitric acid, and ammonium nitrate. Most of the product would be exported to the United States.[73]

U.S.S.R.—Construction was begun at Kemerovo on the first of two ammonia units with a capacity of 404,000 tons per year of contained nitrogen. Creusot-Loire Enterprises of France was building the plant, using a Kellogg process design. Both units were due onstream in 1978.[74] Toyo Engineering Corp. of Japan won a $350 million contract with the U.S.S.R. to supervise the construction of four 1,485-ton-per-day ammonia plants and two 1,650-ton-per-day urea units over a 4-year period.[75] Russian shipbuilders launched the first of seven tankers slated to haul liquid ammonia from the U.S.S.R. to the United States and return with superphosphoric acid. The tankers are being built under a 1973 agreement with Occidental Petroleum Corp., and are expected to be afloat by 1980.[76] Snamprogetti was awarded contracts for three 495,000-ton-per-year urea plants to be built at unspecified locations, probably by 1978. At least two of the plants will be integrated with ammonia units which have been ordered from Snamprogetti.[77] Two large scale ammonia plants were scheduled for completion in 1976 at the Grodno nitrogen complex. The new units will more than triple the existing capacity of 396,000 tons of contained nitrogen. Urea and ammonium sulfate plants were also under construction at the site.[78]

United Kingdom.—The decision to construct a 300-ton-per-day liquid oxygen-nitrogen plant near Glasgow, Scotland, at a total investment of about $11.7 million was announced by the British subsidiary of Air Products & Chemicals, Inc. The plant was scheduled for completion in 1977, and will provide for anticipated industrial growth in Scotland and northern England.[79]

Vietnam, North.—The Hitachi Shipbuilding Co. of Japan reached agreement with the North Vietnamese Government for the construction of a 132,000-ton-per-year nitrogen fertilizer plant.[80]

TECHNOLOGY

Johns Hopkins University scientists were developing a method to make ammonia from air and water on floating platforms by using power produced by tapping the temperature gradient of the oceans. The ammonia plant would be assembled on the ocean thermal energy conversion platform as an adjunct to a hydrogen-producing electrolysis unit. The source of nitrogen for the ammonia synthesizer would result from combining the oxygen in air with about one-seventh of the gaseous hydrogen from the electrolysis plant to form water. The remaining nitrogen and hydrogen are mixed and fed to the synthesizer. A condenser removes most of the ammonia as liquid, and the remaining gases are returned to the synthesizer by a recirculating compressor. A working fluid, such as ammonia, is alternately evaporated by warm surface water and condensed by colder water from the depths. In the vapor form, the working fluid powers the turbines.[81]

New ideas for boosting ammonia plant efficiency were getting intensive study because of rising prices and dwindling supplies of gas. The studies included recovery of purge gases as well as hydrogen from purge gases in the ammonia synthesis loop with cryogenic units; improved insulation materials, particularly for reforming furnaces to reduce maintenance and operating downtime relative to refractory brick; and increased use of computers to closely monitor the hydrogen-to-nitrogen ratio and improve the control of other variables.[82]

Officials of Union Carbide Corp. claimed that its metal-passivating process, used to inhibit corrosion in plants that use monoethanolamine for scrubbing carbon dioxide from synthesis gas streams, could save several hundred thousand dollars annually in an average 1,000-ton-per-day ammonia plant. A number of ammonia and hydrogen plants have converted to the system.[83]

Investigators have been searching for new ways to produce fixed nitrogen by extending or imitating the natural process. A new understanding of the nitrogenase and glutamine synthetase cycles has resulted in some interesting research, including manipulation of these enzymes and the genes that control nitrogen fixation, and indirectly improving nitrogen fixation through improvement of the photosynthesis process by controlling the supply of nutrients.[84]

The government of West Germany will provide funds for a 5-year international program of research into the use of nitrogen fertilizers. Particular attention will be focused on the possible harmful effects they might have on water supplies and food produced, with the hope that optimum application rates can be determined. The research will be carried out in West Germany in conjunction with the International Atomic Energy Organization and many research institutes in developing countries.[85]

The possibility was raised that man's increasing use of chemical nitrogen fertilizers is a greater threat to the ozone layer than chlorofluorocarbon sprays. The amount of ozone, which is formed by ultraviolet rays striking oxygen molecules, is kept in check by nitrogen compounds which act to break up ozone and cause oxygen to reform. The natural release of nitrous oxide and nitrogen by decayed matter replenishes atmospheric nitrogen and supplies the ozone-destroying catalyst. The natural denitrification process could be sharply increased with escalating use of nitrogen fertilizers, thus possibly diminishing ozone.[86]

Because of declining and unsure supplies of natural gas, The Fertilizer Institute called for a 10-year study of ammonia production by coal gasification, to be funded by the National Fertilizer Development Center of the Tennessee Valley Authority. The principal effort would be to improve the economics of the coal-based route since the cost of a 1,000-ton-per-day plant was estimated at $215 million.[87]

The city council of Seattle, Wash., was considering a $30 million, 140,000-ton-per-year ammonia plant, to be built and operated by Coyne Chemical Co., which would utilize municipal solid wastes. The city would be required to build the needed $55 million, 550,000-ton-per-year solid waste processing facility.[88]

Peat

By Donald P. Mickelsen [1]

Peat production in the United States in 1975 was 6% greater than in 1974, principally because of greater output by several of the smaller producers and an increase in the number of active operations. There were seven new operations in 1975, even though several producers were prevented from operating owing to a lack of environmental permits. Production increased in 11 States, with the largest production gains occurring in Florida, New York, Iowa, Colorado, and Massachusetts.

Commercial sales of peat in the United States were 6% higher than in 1974. The quantity of peat sold was 3% less than the amount produced because approximately 26,000 tons went into producers stockpiles. The total value of peat sold, f.o.b. plant, rose 12% to $12.3 million in 1975. The average value of all peat sold increased $0.93 per ton, principally because of higher production costs and a trend to packaging in smaller bags.

Imports dropped more than 11% in 1975. Still, imported peat provided 28% of the peat available for consumption in the United States. Canada provided 98% of the imported peat.

World production was estimated at 223 million tons. The U.S.S.R. was the largest producer, with an output estimated at 211 million tons, or 95%, of the world total.

DOMESTIC PRODUCTION

Peat is broadly classified in the United States as moss peat, reed-sedge peat, and humus, varying according to the type of plant matter from which it was formed and its degree of decomposition. Moss peat is a type that has been formed principally from sphagnum, hypnum, and/or other mosses; reed-sedge peat originated mainly from reeds, sedges, and other swamp plants; and humus peat is too decomposed for identification of its biological origin.

The 41,000-ton increase in 1975 production resulted from a larger output of moss-type peat. Of the reported production, more than 54% was reed-sedge peat, 25% was moss peat, and the remainder was humus.

A 48% increase in the production of moss peat was attributed to the entry of five new producers and an increased output by existing producers in Florida, Colorado, Indiana, Massachusetts, and Washington. This increase offset a 6% decrease in reed-sedge production.

Peat was produced in 22 States in 1975. Michigan remained the largest producer, with 32% of the Nation's output, followed by Florida, Illinois, Indiana, Iowa, and Colorado, ranked in the order named. These States, together with Michigan, accounted for 75% of the total production.

Active operations in the United States increased from 102 to 109, but the average output per plant decreased slightly to 7,080 tons. Over three-fourths of the operations had outputs below the average. Only 32 plants had production in excess of 5,000 tons, and only 5 plants produced more than 25,000 tons.

Production methods used in the United States varied with the size and conditions of the bog being worked. Almost all peat was harvested using conventional earthmoving and excavating machinery, or modified conventional machinery. Power shovels, bulldozers, and front-end loaders were used in drained bogs; draglines, clam shells, and dredges were used in submerged deposits.

---

[1] Mineral specialist, Division of Coal.

Peat bogs are generally covered with water, tree trunks, limbs, and other debris and must be properly cleared and drained before harvesting. In most instances, the bog is drained by constructing a series of feeder ditches and collecting canals so that the prevailing water table can be lowered and controlled. Since the surface of a peat bog is unstable, roads are built across the bog to provide a firm surface for trucks to travel on. The use of special wide-track treads enables other machinery to operate upon the bog surface.

Various harvesting techniques are employed at domestic peat operations. Generally, the peat is harvested by first loosening the top layer of the bog to a depth of approximately one-half inch with a disk, spike, or spring harrow. The loosened peat is then scraped into piles alongside the roads with bulldozers and loaded into trucks with front-end loaders. Other production methods include the use of vacuum harvesters, snowblowing machines, draglines, and dredges.

Peat is usually processed for sale by air drying, shredding, screening and in a few instances, by artificial drying. Processing equipment consists of a variety of screens, shredders, grinders, hammermills, and gas- and oil-fired dryers.

In 1975, 37% of the peat was sold as produced with no processing other than air drying. About 62% was shredded, but only 1% was subjected to thermal drying.

Table 1.—Salient peat statistics

	1972	1973	1974	1975
United States:				
Number of operations	103	98	102	109

CONSUMPTION AND USES

The amount of peat available for consumption remained at practically the same level in 1975, increasing less than 1%. This was principally due to the fact that imports decreased 11% from those of 1974.

Peat was used for a variety of purposes, but 81% of the total commercial sales reported by producers was used for general soil improvement. Among the principal markets for this peat were nurseries and greenhouses, which used peat as a mulch and as a medium for growing plants and shrubs; landscape gardeners and contractors, who used peat for building and maintaining lawns, golf-course greens, and for transplanting trees and shrubs; and garden, hardware, and variety stores, which sold peat to homeowners for mulching and improving lawn and garden soils. The remaining peat was sold principally for use in potting soils, a market that has grown greatly in the past few years along with the household plant industry.

Peat was also used for packing flowers and shrubs, and in mushroom beds. Small quantities were used for earthworm culture, seed inoculant, and in mixed fertilizers.

About 55% of the peat sold commercially by producers was packaged, and packaged peat accounted for 68% of the total value of sales. Package sizes varied greatly, but most producers used 40-pound bags, a change from the 50-pound bags previously used. The use of smaller bags for packaging both peat and potting soils has grown rapidly in the past several years and 5-, 10-, and 20-pound bags of each are commonly being produced for household use. About 69% of the packaged peat sold in 1975 was of the reed-sedge type, 17% was moss, and the remainder was humus.

States leading in sales of packaged peat were Michigan, Illinois, and Indiana. Together, these States reported 79% of total sales of packaged peat. Michigan, the largest producer, had 49% of the total sales.

Of the bulk peat, 64% was reportedly sold for general soil improvement. The remainder of the bulk peat was sold mainly for use in potting soils, for packing flowers and shrubs, and in mixed fertilizers.

PRICES AND SPECIFICATIONS

Prices of peat at individual operations varied greatly in 1975, with the price depending mainly upon the kind of peat sold, the amount of processing, and whether the peat was sold in bulk or packaged form.

The overall average value per ton, f.o.b. plant, for all peat sold in 1975 was $16.49, up from $15.56 in 1974. Most of the increase was attributed to higher average receipts for peat sold in 9 States, with significant increases occurring in Indiana, California, New York, and Ohio.

The average price of bulk peat was $12.00 per ton, an increase of $1.22. Packaged prices increased an average of $0.40 per ton to $20.09. The average price of bulk peat in the United States was influenced mainly by higher overall prices and increased quantities of bulk sales by producers in Illinois, Ohio, and Minnesota. The increase in the unit value of packaged peat was attributed to higher receipts for packaged peat sold by Indiana, California, New York, and Florida producers.

In a few instances, when producers did not report the value of peat sold, the sales value was calculated based upon the average value of a similar type peat sold within the State.

Imported peat had a total value of $23.9 million. This value was 6% greater than in 1974, principally because the average value per ton increased from $69.16 to $82.17.

Although the average value of imported peat was four times that of domestically produced packaged peat, these values are not comparable because of different marketing levels. Also, imported peat has different physical properties than most domestic peat, and it usually is sold on a volume basis rather than by weight. Each 100 pounds of a typical air-dried imported peat will measure approximately 12 bushels, whereas the same weight of a typical domestic peat will measure only 3 or 4 bushels. A few domestic operations, in the northern latitudes, produced peat with properties similar to those of the imported kind.

FOREIGN TRADE

The quantity of peat imported into the United States in 1975 totaled 290,000 short tons. This tonnage was 11% less than that imported in 1974, and the first quantitative drop in imports since 1970. Canada provided the bulk of the peat imports, supplying 98% of the total. Virtually all of the remaining foreign peat was supplied by Europe.

European shipments decreased 48%, owing principally to a substantial drop in shipments from West Germany. West Germany supplied 97% of the peat imported from Europe.

Imported peat was classified according to use, either as poultry- and stable-grade or as fertilizer-grade. Except for a duty of $0.50 per long ton levied on poultry- and stable-grade peat from countries with centrally controlled economies, there was no tariff on peat.

Foreign peat entered the United States through 29 customs districts in 1975, but 89% of the total was shipped through the customs districts of Buffalo and Ogdensburg, N.Y., Detroit, Mich., Pembina, N. Dak., St. Albans, Vt., Portland, Maine, and Seattle, Wash. The largest quantity, 86,000 tons, was shipped through the Ogdensburg district.

WORLD REVIEW

World production of peat in 1975 was estimated at 223 million tons, about 1% more than the output reported for 1974.

The U.S.S.R. was by far the largest peat producer, with an estimated 95% of the world production. According to published U.S.S.R. figures, 145 million tons of peat was produced by State enterprises for agricultural use, and an estimated 66 million tons was used for fuel. Agricultural peat was used for general soil improvement and the manufacture of fertilizers, and fuel peat was used for generating electric power and for industrial and domestic heating.

Ireland ranked second in peat production, with an estimated 7.7 million tons, an increase of 60% from 1974 production. Virtually all of Ireland's production was fuel peat used for generating electric power and for heating households. A small amount of agricultural peat was produced, principally for export.

West Germany, the third-ranking peat producer, with 1.8 million tons, provided about 1% of the world output. Most of the West German production was agricultural peat; only 14% was consumed as a fuel.

Other producers, ranking in output in the order named, were the United States, the Netherlands, Canada, and Finland. However, the combined output of these countries was less than 1% of the total. Although fourth in world production, the United States output was less than 0.5% of the world total.

Since the oil embargo of 1973 and the subsequent increase in fuel oil costs, peat has been seriously studied as a competitive fuel source in some European countries.

Ireland, which is second only to the U.S.S.R. in using fuel peat for generating electricity, is planning to expand its generating capacity about 37% to 587 megawatts by 1980 and develop an additional 40,000 acres of peatlands for fuel peat production. In 1974, Ireland was generating approximately 24% of its electricity using peat as fuel.[2]

---

[2] O'Donnel, S. Ireland Turns to Peat. New Scientist, v. 63, July 1974, pp. 18–19.

In Finland, an attempt to develop an internal energy source has led to the early stages of utilizing peat as a fuel. In 1974, 436 Mw of power was produced, using peat-fired mobile power generators. Finland has developed a dual power system, using peat to provide energy for both electrical generation and municipal heating. This system allows energy-conversion efficiencies of up to 85%. Finland's peat should provide 0.5% of that Nation's energy requirements by 1980.[3]

TECHNOLOGY

The Fuel and Lubricant Research Laboratory of the Technical Research Centre of Finland has been investigating the production of coke and active carbon from peat in the laboratory and in a pilot plant.

In 1975, the State Fuel Centre of Finland began construction of a peat coke plant having an annual capacity of 30,000 tons. The peat coke produced at this plant will be used with metallurgical coal coke for the production of ferric chrome.

Research has found that the production of good peat coke is dependent on the type of peat used and the method of processing. A dense peat, usually having humic characteristics and a low-inorganic content, produces the most economic coke. Mechanical molding of the peat was found to be important since it critically affects the shrinkage. The molding is usually accomplished by using sod- or briquet-production techniques. Molding also reduces the number of pores larger than 100 nanometers produced by air-drying and, along with the adding of alkalic chemicals, can intensify the strength of the air-dried peat, which results in a stronger coke.

---

[3] McLain, L. Finn's Power Policy Offers Added Spark to British Industry. Eng., v. 240, Mar. 13, 1975, p. 26.

Molded peat shrinks approximately 80% when it is air-dried. The shrinkage continues during carbonization, peaking when the organic matter decomposes and gaseous substances are formed. This process begins at about 250°–300° C, is most intensive at about 350°–400° C, but drops off sharply at higher temperatures. A total of 40%–50% additional shrinkage occurs during carbonization.

Peat coke differs from coal coke in that it is about twice as reactive, is more porous, and has a lower sulfur content. It also has a higher electrical resistance owing to its varied carbon structure. For this reason, peat coke can be used for smelting silicic and chromic alloys in electric furnaces. Its high reactivity also allows it to be mixed with coal coke to increase output. The use of peat coke is limited by its poor strength properties and higher price, although current energy costs have made it more competitive.[4]

The State Fuel Centre is also utilizing peat to combat oil pollution. Finland has had problems with accidental oil spills amounting to hundreds of tons of crude and heavy fuel oil. During the winter, there is no way of cleaning up these spills other than burning; however, this is difficult since the spilled oils become emulsified with the cold water by wave agitation and develop a high water content. Also, after floating for as long as 2 days, the oil layers are sufficiently cooled by the underlying water to make the oil difficult to ignite. Peat, saturated with light oil or petroleum, can be spread upon the oil slick and burned in order to provide enough heat to ignite the oil. The peat ash also continues to absorb the oil, allowing it to keep burning.

Since 1973, a dried, compacted peat has been packaged in 6-cubic-foot bags at the State briquet factory in Kihnio, Finland. These bags are being stored for emergency use along waterways, at ports where oil is being handled, and on land to combat oil pollution.[5]

In Finland, 436 Mw of electricity were produced in 1974, using peat-fueled mobile power generators connected to gas turbines manufactured in Italy.[6] Scotland is also investigating the use of mobile, gas-turbine-based units in order to utilize Scottish peat resources for generating electricity. These gas turbines burn dried, pulverized peat in a near-stoichiometric input of air, to insure a reasonably complete combustion. The hot products of combustion (POC) are passed through a chamber of air-dried peat to further dry it. The POC, in turn, creates steam from the moisture it picks up, thereby cooling itself so that the steam-POC mixture is at a suitable temperature for entering the turbine. The peat is transferred from chamber to chamber in the system by the use of fluidic switches, which are not susceptible to corrosion, while the blades of the turbine itself are sweat-cooled to prevent ash deposits from forming.[7]

In the United States, the Hussong-Walker-Davis Co. of Cornwells Heights, Pa., has experimented with peat as a medium for treating dye-house effluent. Tests performed using the Hussong-Couplan process, in which peat is used as the filtering agent, resulted in the removal of 99.6% of the color, 100% of the turbidity, 98.7% of the chemical oxygen demand, 95% of the biological oxygen demand, 87.8% of the total oxygen demand, 97.7% of the phosphates, and 98.1% of the suspended solids. The peat filters reduced cyanide 100% and heavy-metal pollutants as follows: Hexavalent chromium, and trivalent chromium, copper, nickel, and mercury, 99.9%; cadmium and lead, 99.6%; iron, 99.2%; zinc, 98.9%; and antimony, 98.3%.

The Hussong-Couplan system is based on passing effluent through the scrubbing action of a moving mat of peat. Since most of the pollutants are in solution, they are either chemically adsorbed by the peat or form an insoluble complex salt through ionic bonding. The process consists of preparing peat mats by producing a water-peat slurry in a weight ratio of 100:1. The slurry is deposited on a moving, perforated belt, which allows the excess water to drain off, leaving a uniform mat of peat. The mat moves under discharge pipes that spray the effluent through the peat. The effluent is passed through the peat twice, with the first-pass effluent being collected in basins and stored in tanks between passes. After the second pass, the cleaned liquid is either recycled or discharged.

The resulting spent peat can be disposed of in environmentally sound ways. It can be buried in sanitary landfills safely, since the metal pollutants are in an insoluble form. Or it can be dried and burned and the heavy-metal pollutants recovered. The used peat is the only byproduct of the system.

The Hussong-Couplan system comes in modular, self-contained units 8 by 16 by 9 feet high, and has a capacity of handling 110,000 gallons of effluent per unit in a 24-hour period. The system is capable of meeting the requirements of the U.S. Environmental Protection Agency.

Since the supply of clean water is expected to decrease in the future, recycling water for industrial purposes will become more important in the future.[8]

Perlite

By Arthur C. Meisinger [1]

Although the quantity of crude perlite mined in the United States in 1975 was 706,000 tons, the second highest tonnage on record, the tonnage of crude ore sold and used by producers was nearly 8% less than the record high quantity (555,000) established in 1974. Value of crude perlite sold or used, however, was a record $7.28 million, or $257,000 more than the previous record value set in 1974. Deposits in New Mexico supplied 85% of the total crude perlite mined in 1975.

Value of expanded perlite sold or used in 1975 was $34.3 million, a new record that exceeded the old record high value of $30.8 million (revised) in 1974 by $3.5 million. Illinois continued to be the leading State in the production of expanded perlite.

The newly reopened Socorro, N. Mex. mining operation of Grefco, Inc., made its first shipment of crude ore in December, and the new processing plant is expected to be onstream in 1976.

DOMESTIC PRODUCTION

Crude perlite was produced by 11 companies at 12 mines in 6 States. The quantity of crude ore mined was 706,000 tons, the second highest tonnage on record and 4% greater than the quantity (676,000 tons) mined in 1974. New Mexico continued as the primary producing State with 85% of the crude perlite mined in 1975, followed by Arizona, California, Colorado, Nevada, and Idaho in descending order of production.

The quantity of crude perlite sold or used by domestic producers was 512,000 tons, 8% less than the record high 555,000 tons sold or used in 1974. The value of crude perlite sold or used, however, was a new record of $7.28 million and exceeded the old record high value of $7.02 million in 1974 by $257,000.

Expanded perlite was produced at 69 plants in 29 States in 1975 compared with 76 plants in 30 States in 1974. The quantity of expanded perlite produced declined for the third straight year and was 22,000 tons lower than the 1974 figure. The quantity of expanded perlite sold or used in 1975 by producers was 394,000 tons, the lowest quantity since 1971. Value of expanded perlite sold or used, however, set an alltime high of nearly $34.3 million, compared with the 1974 record value of $30.8 million (revised).

The leading States in descending order of expanded perlite production in 1975 were Illinois, Texas, Mississippi, Kentucky, Pennsylvania, New Jersey, Colorado, California, Florida, and Indiana.

The new Socorro, N. Mex. perlite mining operations of Grefco, Inc., Los Angeles, Calif., went onstream at yearend. Processing of the crude ore is expected to begin in 1976.

Producers of crude perlite during the year were Filters International, Inc., Harborlite Corp., and Guzman Construction Co. with operations near Superior, Ariz.; American Perlite Corp., with deposits in Inyo County, Calif.; Persolite Products, Inc., Rosita, Colo.; Oneida Perlite Corp., near Malad City, Idaho; Delamar-Mackie Perlite, Caliente, Nev.; United States Gypsum Co., with operations at Lovelock, Nev., and Grants, N. Mex.; and Silbrico Corp., Johns-Manville Sales Corp., and Grefco, Inc., with operations in Taos County, N Mex.

CONSUMPTION AND USES

Domestic consumption of expanded perlite was 394,000 tons, or 6% less than that in 1974. A percent distribution by end use is shown in table 3. Three major end-use categories (filter aids, horticultural aggregates, and formed products) showed significant gains in 1975, but four end-use categories (plaster aggregates, low-temperature insulation, masonry and cavity fill insulation, and other uses) declined from 1974 in percent of total consumption. Use of perlite in concrete aggregates (8%) and in fillers (1%) in 1975 was unchanged from that in 1974. Other uses reported in table 3 include primarily insulation board and a variety of uses such as paint textures, foundry castables and bonding agents, polishing compounds, and fines for various industrial uses.

Table 3.—End use of expanded perlite
(Percent)

Use	1974	1975
Filter aids	17	21

Concrete aggregate	8	8
Horticultural aggregate	6	8
Low-temperature insulation	5	1
Masonry and cavity fill insulation	4	3
Fillers	1	1
Formed products	8	11
Other [1]	42	39

[1] Includes insulation board.

PRICES

Producers sold crushed, cleaned, and sized crude perlite to expanding plants at an average price of $14.26 per ton, an increase of $1.37 per ton over that in 1974. Crude perlite used by producers in their own expanding plants was valued at $14.19

per ton, an increase of $1.76 per ton compared with that of 1974. The weighted average price of both categories was $14.22 per ton compared with $12.66 per ton in 1974.

Expanded perlite sold or used, according to expanders, was valued at $86.96 per ton compared with $73.44 per ton (revised) in 1974. Average values for expanded perlite by States ranged from $36 to $186 per ton, compared with the 1974 range of $28 to $174 per ton.

WORLD REVIEW

Greece.—Excluding the U.S.S.R., Greece is the leading producer of crude perlite in Europe. Although data on perlite production were not available for 1975, the country produced 231,400 tons of crude perlite in 1974 compared with 273,300 tons in 1973, and processed 125,900 tons for export compared with 138,600 tons in 1973. Greek producers exported 140,250 tons of perlite in 1974, of which about 10% was unprocessed ore.

Mexico.—The quantity of crude perlite produced increased substantially (57%), from 13,400 tons in 1974 to 21,000 tons. Four companies in Mexico expanded perlite at two plants near Mexico City and one plant each in the States of Monterey and Sonora.

Philippines.—Output of crude perlite from the Trinity Lodge Mining Corp. deposit was 733 tons compared with 1,248 tons in 1974. Perlite Minerals and Industrial Corp. at Ermita, Manila, was reported to be studying the feasibility of a joint venture for processing, expanding and marketing perlite for domestic construction products, such as ceiling tiles and insulation board.

Turkey.—Data on mine production of perlite were not available for 1975, but approximately 22,000 tons was mined in 1974, and an estimated 16,500 tons was reported to have been exported by Turkey. About 90% of the annual crude perlite output comes from mining operations in the West Anatolian region of the country near the Aegean Sea.

United Kingdom.—Tiling Construction Services Ltd. (Tilcon) announced in 1975 the opening of the company's new perlite expanding plant at Kirkby, near Liverpool, England.[2] Tilcon also operated an expanding plant in Buxton, Derbyshire, England, for producing a lightweight perlite mortar aggregate that is marketed under the trade name, Limelite. The Kirkby plant is designed to produce filtration-grade perlite and various industrial perlite products for market areas in Scotland, the north of England, and other areas of the United Kingdom.

Petroleum demand[4] in 1975 was moderately below 1974 levels as increases in motor gasoline consumption failed to offset marked declines for other major products. Reduced demand for distillate fuel oil and residual fuel oil, for example, resulted in part from a mild winter and in part from the economic recession. The net result was that overall domestic demand declined in 1975 to about 16.3 million barrels per day (bpd) from 16.7 million bpd in 1974, or about 2%. Production of crude oil, lease condensate, and natural gas liquids also declined, however, making it necessary to increase crude imports to augment new supply to meet demand.

New supply consists of domestic production of crude oil, lease condensate, and natural gas plant liquids, plus imports. In 1975, imports accounted for 37% of total new supply. In 1972, a year before the

[4] Certain terms as used in this chapter are more or less unique to the petroleum industry. Principal terms and their meanings are—

Total demand.—A derived figure representing total new supply plus decreases or minus increases in reported stocks. Because there are substantial consumers' stocks that are not reported to the Bureau of Mines, this figure varies considerably from consumption as reported by the Federal Highway Administration of the Department of Transportation.

Domestic demand.—Total demand less exports.

New supply of all oils.—The sum of crude oil production plus production of natural gas liquids, plus benzol (coke oven) used for motor fuel, hydrogen, and other hydrocarbons, plus imports of crude oil and other petroleum products.

Transfers.—Crude oil conveyed to fuel-oil stocks without processing, or reclassification of products from one product category to another.

All oils.—Crude petroleum, natural gas liquids, and their derivatives.

Exports.—Includes shipments to U.S. territories, possessions, and free trade zones.

Imports.—Includes receipts from U.S. territories, possessions, and free trade zones.

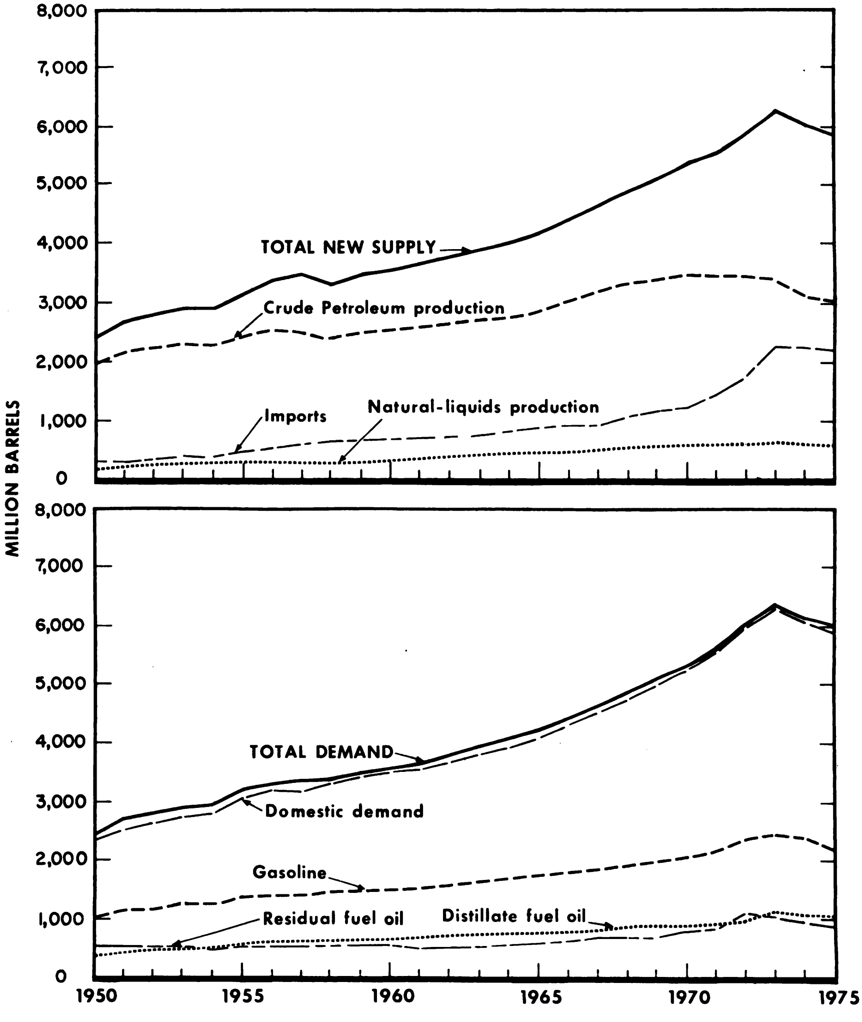

Figure 1.—Supply and demand of all oils in the United States.

Arab oil embargo, imports accounted for nearly 30%. Crude oil imports averaged 4.1 million bpd in 1975, an increase of 18% over the 1974 level. Other imports, such as refined products, unfinished oils, and plant condensate, declined 27% as domestic refineries ran more crude oil to produce larger volumes of refined products.

Refineries in 1975 operated at 81.7% of operable capacity. This ratio is obtained by relating crude runs to stills in 1975, averaging 12,442,000 barrels per day (bpd), to the total operable capacity at the end of 1975 of 15,236,000 bpd: if the operable but shutdown capacity is omitted from the total, the operating ratio increased to 83.7% in 1975.

Four lease sales were conducted in 1975 by the Bureau of Land Management, U.S. Department of the Interior. These sales, held in February, May, July, and December, involved 1,679,877 acres, and the bonuses aggregated over $1 billion, as shown in the following tabulation:

Offshore location	Date	Offered		Leased		Total high-bid accepted
		Tracts	Acreage	Tracts	Acreage	
Texas	Feb. 4	515	2,870,344	113	626,585	$274,690,955
Louisiana–Texas	May 28	283	1,346,432	86	406,942	232,916,050
Do	July 29	345	1,772,958	66	336,301	163,214,006
Southern California	Dec. 11	231	1,258,189	56	310,049	417,312,141
Total		1,374	7,247,923	321	1,679,877	1,088,133,152

Drilling activity accelerated in 1975. The weekly activity of 1,659 rotary rigs was the highest in 12 years, according to the Hughes Tool Co. The American Petroleum Institute (API) reported there were 16,408 oil wells completed in 1975, an increase of 28%. There were 7,580 gas wells drilled in 1975, 5% more than in 1974.

A very large segment of drilling activity related to "infill" development well drilling; that is, drilling in known fields. Much of this activity was attributed to the "two tier" pricing of crude oil. On one tier was "old" oil priced at $5.25 per barrel and on the other tier was "new" oil priced in December 1975 at $12.95 per barrel. In 1975, there were three classes of uncontrolled oil: New, released and stripper. Subsequent legislation in the Energy Policy and Conservation Act eliminated the "released" category, but new oil and stripper oil remained in the FEA classification.

According to API estimates, proved reserves of crude oil declined for the fifth consecutive year as production withdrawals continued to exceed additions to reserves.

Work on the Trans-Alaska Pipeline was progressing, and the target date for startup for moving crude to Valdez, Alaska was mid-1977. Initial throughput was expected to average about 600,000 bpd in 1977.

Reserves of 32.7 billion barrels at yearend 1975 represented a reserve-to-production ratio for crude oil of 11:1 (based on 1975 production).

Refinery operable capacity at yearend 1975 in the United States and Puerto Rico amounted to 15.5 million bpd, up nearly 2% from yearend 1974. Following the discontinuance of import quotas on crude oil and petroleum products, many refiners announced expansion plans that could increase throughput capacity to 16.1 million bpd. Most of the proposed new capacity is scheduled to run imported crude oil.

CRUDE PETROLEUM

PRODUCTION

Production of crude oil (including lease condensate) in 1975 continued the downtrend that began after 1970. Total production in 1975 was about 3.1 billion barrels, nearly 5% below that of 1974. There were declines in 22 of the 31 oil-producing States. The sharpest decline occurred in the gulf coast region of Louisiana, which had a drop of 80 million barrels, or 11.5%. In Texas, gains in West Texas failed to offset declines in other parts of the State, so there was a net decline in 1975 of 40.2 million barrels, or 3.2%.

The overall decline continued in 1975 but at a more moderate rate, particularly in Texas. On the plus side, production has increased in Alabama, Colorado, Florida, Michigan, Ohio, Utah, and in the San Joaquin Basin of California over each of the past 5 years and these six States and one area produced 20 million barrels more crude oil in 1975 than in 1974.

DRILLING ACTIVITY

Drilling activity in 1975 had 23,988 successful oil and gas well completions, an increase of 20%. There were 16,408 oil wells completed in 1975, a 28% increase of 3,624 wells. Gas well completions were 7,580, 5% above the 1974 results.

Development well completions, both oil and gas, increased 21% above 1974 levels and accounted for 21,845 wells, or 91% of the total well completions in 1975. Of 21,845 well completions, 15,436 were completed as oil wells, a 29% increase over 1974. More than 6,000 (37%) of the total successful oil wells were completed in Texas. California was second in importance with 1,854 oil well completions,

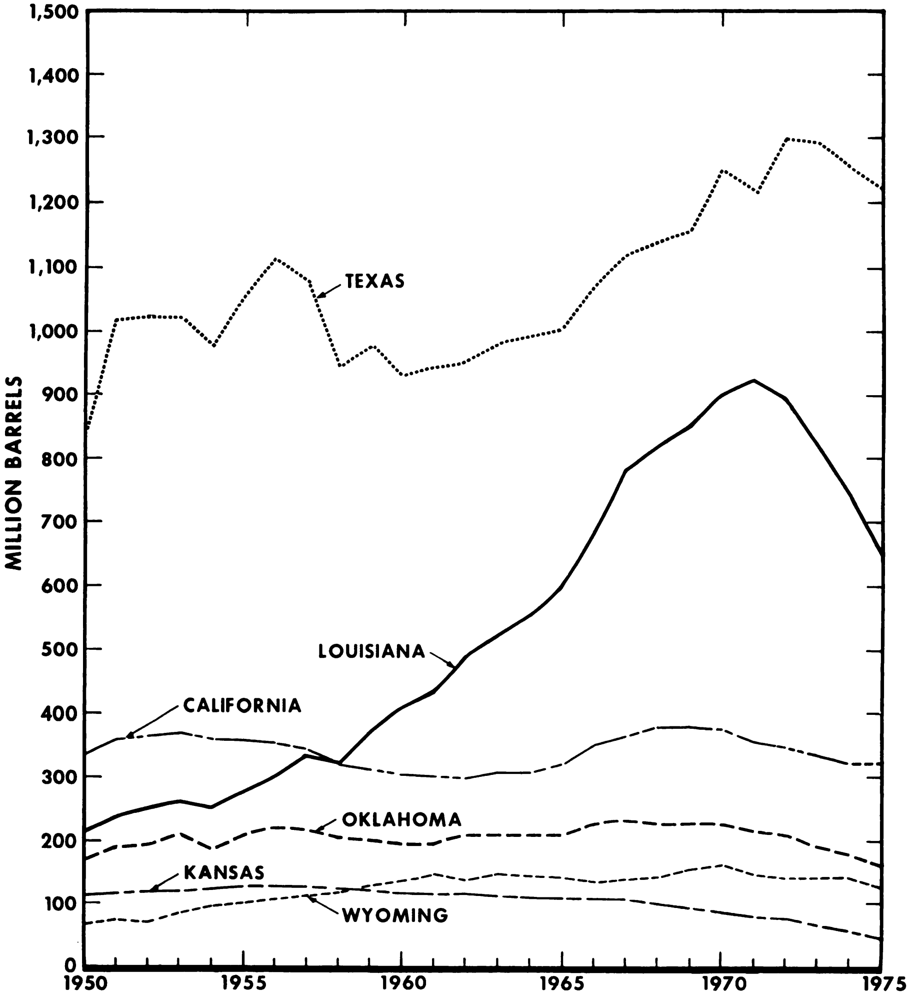

Figure 2.—Production of crude petroleum in the United States, by principal producing States.

and in Oklahoma, 1,743 oil wells were completed.

Development oil well completions for 1970–75 are shown in the following tabulation, by quarter:

Year	January–February	April–June	July–September	October–December	Total
1970 ----------	3,088	2,943	3,115	3,125	12,230
1971 ----------	2,804	2,679	2,617	3,089	11,207
1972 ----------	2,789	2,729	2,664	2,452	10,622
1973 ----------	2,310	2,093	2,333	2,542	9,283

There were about 500,333 oil wells producing at the end of 1975, compared with 497,631 at yearend 1974. This was a continued increase in the number of oil wells producing. Production of all produc-

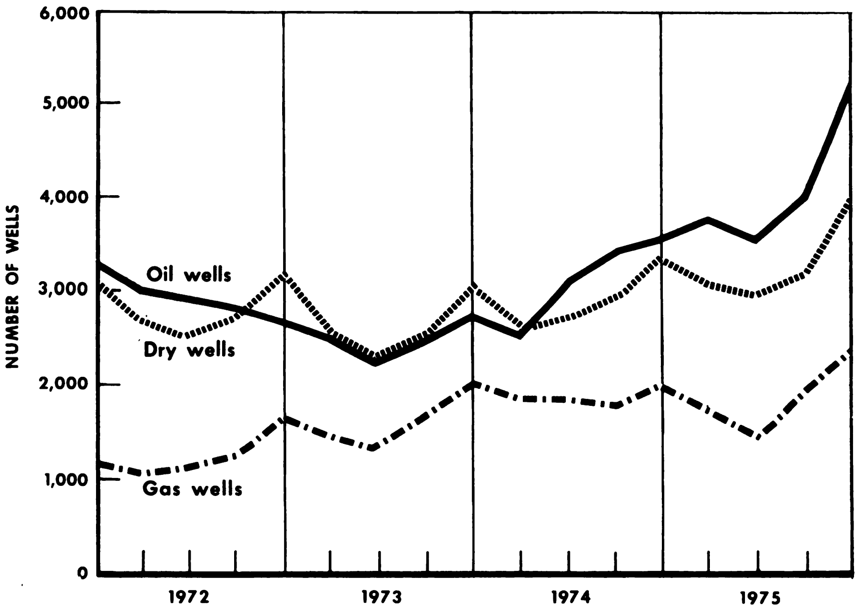

Figure 3.—Wells drilled for oil and gas in the United States, by quarter.

ing oil wells averaged 16.7 bpd in 1975, compared with 17.6 bpd in 1974.

Stripper wells, which are wells producing 10 bpd or less of oil, at the end of 1975 numbered 367,872, or 73.5% of all oil wells, according to the National Stripper Well Survey, a joint project of the Interstate Oil Compact Commission and the National Stripper Well Association.

Stripper wells recovered oil from 9,218,949 acres and accounted for 394,162,941 barrels of the total domestic crude oil output in 1975. Average production per well was 2.93 bpd. Stripper well abandonments totaled 13,478 in 1975.

RESERVES

The API Committee on Petroleum Reserves estimated recoverable reserves of crude oil as of December 31, 1975, to be 32,682 million barrels, a decline of 1,568 million barrels, or 4.6% for the year.

Gains in proved reserves occurred in six States, led by California, which added 90.5 million barrels. Losses in proved reserves occurred in 22 States. In those States with significant reserves, the largest losses occurred as follows (in million of barrels): Texas, 922; Louisiana, 400; Utah, 43; New Mexico, 37; and Wyoming, 26. A 5-year time series on proved reserves is available in table 12.

Indicated additional reserves from known reservoirs are those potentially available crude oil reserves in known reservoirs in excess of proved reserves. Engineering knowledge and judgment indicate that these additional reserves will be economically available by application of fluid injection and other improved recovery techniques. In addition to proved crude oil reserves, the API estimates indicated additional reserves to be 5,022 million barrels. Texas accounted for 1,867 million barrels, or 37.2%; California followed closely with 1,863 million barrels, or about 37.1%. Other States were New Mexico, 350 million barrels, or 7%; Oklahoma, 227.5 million barrels, or 4.5%; and Wyoming, 182 million barrels, or 3.6%.

CRUDE SUPPLY

Total receipts of crude oil at refineries in 1975 were 4,546.2 million barrels, or 12.5 million bpd, an increase of 110 million barrels, or 301,000 bpd. In 1975, refinery runs to stills increased 112.7 million barrels, or 309,000 bpd, as shown in table 19. Reflecting the continued phaseout of Canadian crude oil exports to the United States, overland receipts of crude oil from Canada declined 69.6 million barrels in 1975, or 24%, as shown in table 61. Conversely, imports of crude oil from Mexico jumped from less than 1 million barrels in 1974 to over 25 million barrels in 1975. Foreign receipts from overseas sources were up 229.0 million barrels, or about 627,000 bpd, and more than one-half of that increase originated in Africa as a result of Libya resuming exports of crude oil to the United States. Although the Arab oil embargo was lifted in the spring of 1974, Libya did not lift its restrictions on exports to the United States until early 1975. PAD district I, with refinery centers around New York Harbor and in the Delaware River Valley, received 30% of total crude oil imports, and PAD III, the gulf coast, followed closely with 29%. Refineries processed 4,541.4 million barrels (12.4 million bpd) of crude petroleum of which 67% was of domestic origin (table 19).

REFINED PRODUCTS

SUPPLY AND DEMAND

Demand for petroleum products averaged 16.3 million bpd in 1975, which was 2% below 1974 levels and about 1,017,000 bpd less than in 1973. Most of the decrease resulted from the mild 1974–75 winter season. Lower distillate fuel demand, coupled with decreased use of residual fuel oil and LP gases and a sharp decline in asphalt demand, more than offset the rise in motor gasoline demand during 1975.

MOTOR GASOLINE

Motor fuel demand, as estimated by the Bureau of Mines, averaged nearly 6.7 million bpd in 1975, which was about 2% above demand of 6.5 million bpd in 1974.

The Federal Highway Administration (FHA) also compiles data on gasoline consumption. These data, based on State taxation reports at the wholesale level, include highway use and nonhighway use of motor fuel and differ from Bureau of Mines estimates since only part of secondary stocks relating to independent bulk terminals are included in the Bureau's reports. Secondary stocks held by jobbers, dealers, service station operators, and consumers are excluded from the Bureau's calculations. FHA estimated that gross consumption of motor gasoline, for both highway use and nonhighway use, averaged 6,802,000 bpd in 1975, compared with 6,644,000 bpd in 1974 (table 23).

Federal Energy Administration (FEA) restrictions on motor gasoline which were under the Emergency Petroleum Allocation Act of 1973 (Public Law 93–159) were continued under the Energy Policy and Conservation Act (EPCA) which was enacted unto law (Public Law 94–163) on December 22, 1975.

AVIATION FUELS

Aviation Gasoline.—The downtrend in demand, which dates back a decade, continued in 1975. With the transition from piston to jet and propellerjet engines, demand shrank 76% from 120,000 bpd in 1965 to 38,540 bpd in 1975. Over this period, airline use of aviation gasoline as reported by dealers declined from 33,000 to 2,300 bpd and military use declined from 60,000 to 9,400 bpd. Military use accounted for 53% of shipments in 1965 and about 25% in 1975, as shown in table 26.

Commercial Jet Fuel.—By far, the greatest use of kerosine is in commercial kerosine-type jet fuel. This product is a kerosine with restrictions on the content of aromatics and naphthas as stipulated in ASTM–D 1655 specifications. The product has a very low freezing point and includes military JP–5 jet fuel.

Shipments of kerosine-type jet fuel recovered moderately in 1975 after a sharp drop in 1974 but were still below the levels of 1972 and 1973, reflecting in part at least the impact of the economic recession. Shipments kerosine-type for commercial use in 1975 averaged 715,000 bpd compared with 694,000 bpd in 1974 (table 26).

Production of the kerosine-type jet fuel averaged about 691,000 bpd in 1975, a 7.9% increase over 1974. At the same time

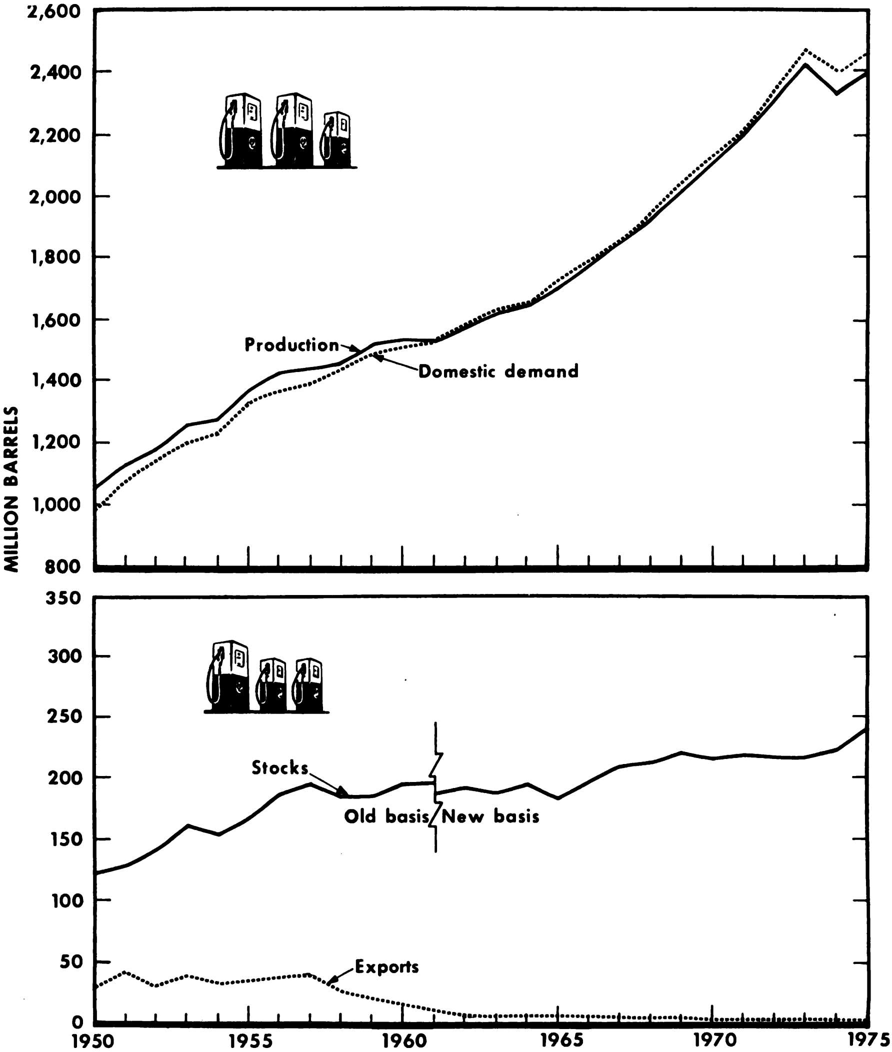

Figure 4.—Production, domestic demand, stocks, and exports of gasoline in the United States.

imports, were cut back about 23% (table 27).

The use of jet engines as gas turbines to generate electric power is expanding. Nearly 2.5 million kilowatts of capacity in gas turbine plants was either in the planning stage or under construction in 1975. Another 2.5 million kilowatts was scheduled for 1976. At the same time, however, the use of kerosine-type jet fuels is decreasing. Prices for kerosine-type jet fuel have increased more sharply than for No. 2 and No. 4 distillates so that utilities are using more distillates and have cut back on the use of commercial kerosine-type jet fuels as follows (thousand barrels):

1972	8,800
1973	6,300
1974	5,200
1975	3,200

Naphtha-type jet fuel shipments that are primarily for the military declined slightly in 1975 to 238,000 bpd from 249,000 bpd in 1974. In addition, the military imported in 1975 an additional 10.2 million barrels; in 1974, direct imports totaled nearly 8 million barrels.

Naphtha-type jet fuel is in the heavy naphtha boiling range with an average gravity of 52.8° API and 10% to 90% distillation at 210° F to 420° F and conforms to ASTM–D 1655 and military specifications MIL–F–5624 and MIL–T–56246. It includes military jet fuel, JP–4.

The allocation program and price controls administered by the FEA have been changed. Controls on naphtha-type jet fuel have been lifted by FEA, but controls remain on kerosine-type jet fuel and aviation gasoline.

LIQUEFIED GASES, ETHANE AND ETHYLENE

Liquefied gases are derived from two sources; those produced at refineries are called liquefied refinery gases to distinguish them from liquefied petroleum gases obtained by processing natural gas. The liquefied petroleum gases (LPG) are all paraffins (propane, butane, and isobutane). The liquefied refinery gases (LRG) also contain paraffins but may also contain unsaturated hydrocarbons; that is, the olefins (propylene, butylene, ethylene, etc.). The paraffins may be used as fuel (including as a blend with motor gasoline) or as feedstock at petrochemical plants. The olefins are used primarily as petrochemical feedstocks.

Demand for ethane (including ethylene) declined nominally in 1975. Ethane is used primarily to make ethylene, a building block for petrochemicals.

Domestic demand for LPG and LRG in 1975, excluding that blended into other products at refineries or terminals, was nearly 1 million bpd, compared with 1.1 million bpd in 1974. Propane accounted for 79% of liquefied gas demand in 1975, but if refinery propane and proyplene is deducted the percentage shrinks to 56%.

Propane was available during the heating season because of the combined effects of allocation, high prices, mild winter weather, and the economic recession. Furthermore, stocks of plant propane totaled 64.8 million barrels at yearend, which was 8% more than 1973 stocks. In 1975, however, production of propane and other natural gas liquids was affected by the decline in natural gas production.[5]

Demand for plant propane declined 5.7% to 554,923 bpd. Production at gas processing plants in 1975 declined only 2.9%, so by the end of 1975 there was a buildup in stocks at plants to 76 million barrels, or 17.4% above the 64.8 million of a year earlier.

Mandatory propane allocation and price controls administered by the FEA continued in 1975. The establishment of new base prices resulted in a lower 1975 average unit value.

Presidential Proclamation 4317, dated September 24, 1974, provided for the tariff fee on natural gas liquids (NGL) imports (excluding propane) to increase to 18 cents per barrel from 15.5 cents per barrel effective May 1, 1975. However, Presidential Proclamation 4341, dated January 23, 1975, estimated a tariff fee of 21 cents per barrel on NGL imports (excluding propane) effective February 1, 1975.

KEROSINE

A mild 1974–75 heating season was reflected in a 9.9% decline in demand for kerosine in 1975. Demand dropped from 176,300 bpd to 158,900 bpd. In 1975, refineries produced kerosine at an average rate of 159,000 bpd, which was only slightly below 1974 daily production of 155,000. FEA allocation regulations applicable to kerosine were withdrawn by FEA. About 78% of the domestic demand for kerosine (including range oil) is for space heating. Domestic demand for kerosine has been in a downtrend for many years. However, this trend could be arrested if present users decide against converting to other forms of energy such as LPG and electric power because of sharp increases in prices.

DISTILLATE FUEL OIL

When produced by conventional distillation procedures, distillate has a boiling range from 10% at 300° F to 90% at

---

[5] Data are available for 1975 in the following Bureau of Mines Mineral Industry Surveys: Natural Gas, Monthly; Natural Gas Liquids, Monthly; and Petroleum Statement, Monthly; and also in the Bureau of Mines Minerals Yearbook Chapter on Natural Gas Liquids.

675° F. Included are Nos. 1 and 2 heating oils and diesel fuels. No. 4 fuel oil, which is a blend of distillate fuel oil and residual fuel oil, is used extensively in smaller industrial plants because it does not require preheating.

The decline in general business activity coupled with a mild 1974–75 winter season resulted in 3.5% decline in demand for distillate from 2.9 million bpd in 1974 to 2.8 million bpd in 1975. The sharpest decline (23%) occurred in the use by electric utilities, from 232,000 bpd in 1974 to 178,600 bpd in 1975. Likewise, use by the railroads dropped from 282,000 bpd in 1974 to 255,000 bpd in 1975, or 9.5%. Trends in distillate fuel sales for the 1971–75 period are shown by end-use sector in table 31.

Electric utilities used significant quantities of distillates in their gas turbines and internal combustion generating equipment as shown in the footnotes to table 31.

Stock levels were more than ample so that production of distillates by refineries were cut back slightly as indicated in table 32. However, imports were reduced 47% to some 153,300 bpd in 1975 from about 289,300 bpd in 1974. With supplies returned to normal levels, the FEA relaxed its controls on distillate fuel oils but retained the authority to re-impose regulations if they consider it necessary.

RESIDUAL FUEL OIL

Residual fuel oil demand, sensitive to the general level of industrial activity, dropped in 1975 by 206,000 bpd, or 7.8% below 1974 levels (table 33). The use of residual fuel by electric utility companies accounted for over one-half of total use. Heating accounted for 17.3% and industrial use for 12.5%. Utility use in 1975 declined only 4.3%, but industrial use dropped nearly 22% and heating use declined 10%.[6] During 1975, there were two significant developments related to residual fuel oil. The first was the 15% increase in production by U.S. refineries. Secondly, domestic production of residual fuel oil in 1975 exceeded imports for the first time since 1963. Residual fuel oil with a sulfur content of 1.00% or less accounted for 604,000 bpd, or 49% of production. About 338,000 bpd, or 27%, had a sulfur range from 1.01% to 2.00%. Imports in 1975 averaged 1.2 million bpd compared with 1.6 million bpd in 1974, a drop of 25%. Nearly one-half of residual fuel oil imports were received into the Central Atlantic States, and 57.6% was in the low-sulfur range of 0% to 0.50%.

With production up sharply and demand down nearly 8%, by yearend 1975, stocks had built up to levels nearly 7% above those of 1974. Stocks at yearend 1975 were equivalent to a 27-day supply compared with a 20-day supply at the end of 1974. This improvement in supply induced the FEA to relax controls on residual fuel oil similar to the action taken on distillate fuel oil. The FEA, however, reserved the authority to re-impose price and allocation controls if necessary to attain the objectives of the Emergency Petroleum Allocation Act of 1973 (EPAA). This is similar to the authority retained for distillate fuel oil.

OTHER PRODUCTS

Petrochemical Feedstocks.—In 1975, petroleum refineries produced nearly 122.2 million barrels of petrochemical feedstocks. Domestic demand approximated 116.8 million barrels, which was 15.7 million barrels, or nearly 12%, below the 1974 levels as shown in table 35. Naphtha-400° constituted nearly 46% of demand in 1975 (Table 22).

Special Naphthas.—Special naphthas are used primarily as paint thinners, cleaning agents, and solvents. In 1975, as shown in table 34, domestic demand was 27.5 million barrels, a drop of nearly 4.5 million barrels, or 14% below the 32.0 million barrels in 1974.

Lubricants.—Total demand for lubricants in 1975 dropped nearly 12% to 50.2 million barrels from the near 56.7 million in 1974. Exports fell 24% to 9.1 million barrels and domestic demand declined 6.5 million barrels, or 11.5%, as indicated in table 36.

There are 44 refineries in the United States and 1 in Puerto Rico with a finished lubricant manufacturing capacity of 227,650 bpd. This is only 13,200 bpd higher than the capacity levels which prevailed at the beginning of 1970. This modest 1.2% growth rate is understandable. The

---

[6] U.S. Bureau of Mines. Sales of Fuel Oil and Kerosine in 1975. Mineral Industry Surveys, Sept. 17, 1976, 14 pp.

United States dominated the lubricants industry, producing 80% and consuming 60%. Exports were the prime outlet into the 1960's but between 1967 and 1975 exports decreased because construction of refineries in foreign countries was gathering momentum and many of these plants included facilities to manufacture finished lubricants. Exports from the United States dropped from 51,200 bpd in 1967 to nearly 25,000 bpd in 1975, or 51.3%. With demand down and exports declining, production dropped 20.5% in 1975. Lubricant-producing facilities operated at 67.6% of capacity in 1975.

Waxes.—Demand for waxes slackened in 1975 to 6,076,000 barrels or 16,600 bpd, a decline of 10.7% from the 18,600 bpd of 1974 (table 37). The economic recession and the decline in business were reflected in weak wax demand for 1975. With the recovery evidenced subsequently, there has been some improvement in demand, both in total and domestic. Paper converting accounts for about one-half of wax end use.

Petroleum Coke.—Petroleum coke is reported by the Bureau of Mines as catalyst coke and as marketable coke; catalyst coke is a noncommercial coke, which cannot be recovered and marketed because it forms on the catalyst during the cracking of charging stock in the cracking unit of a refinery. This carbon is burned off the catalyst in the regenerator section of a cracking unit, and the coke is used as a refinery fuel without ever being seen. However, production of catalyst coke is shown in order to complete a supply and demand balance.

Production of both catalyst coke and marketable coke totaled 129,241,000 barrels in 1975, a 4.4% increase over that of 1974. About 51% of production, or 66.5 million barrels, was marketable coke. Exports of petroleum coke, however, declined in 1975 to 37.3 million barrels, or 9.8% below the 41.2 million barrels exported in 1974, as shown in table 38.

Nearly 25% of exports (9.2 million barrels) went to Japan, a decrease of 25% from the 12.3 million shipped in 1974. Exports to Canada also decreased 11.5% from the 5.2 million barrels shipped in 1974. Shipments to Europe were up slightly as a sharp rise in shipments to the Netherlands offset declines to West Germany and to Denmark, as indicated in table 59. Other changes between 1974 and 1975 are shown in table 59. Volumewise, marketable petroleum coke is our largest petroleum product export. It accounted for about 50% of the 74.3 million barrels of petroleum products exported in 1975.

Marketable coke may be raw or green coke or it may be calcined; that is, put through a roasting process in the presence of a flame to drive out the volatile impurities. There are three main outlets for marketable petroleum cokes: (1) Use as fuel, (2) manufacture of carbon products such as electrodes for metallurgical furnaces and silicon carbide abrasives, and (3) export. Calcined petroleum coke is used as a conductor at elevated temperatures by aluminum and steel companies and it is usually purchased on a custom basis. There is virtually no spot market for petroleum coke. Most calcined petroleum coke plants are located adjacent to petroleum refineries. Estimated production of calcined petroleum coke in 1975 was 6,650,000 short tons, or nearly 4% higher than in 1974.

Asphalt and Road Oil.—As a result of a continued slackening in road construction, asphalt and asphaltic products shipments in the United States in 1975 declined 11.1% from 31.0 million short tons (5.5 barrels=1 short ton) to 27.6 million short tons.

Sales of petroleum asphalt paving products for consumption in 1975 decreased 12.8% from 24.6 million short tons to 21.5 million short tons in 1975. Sales of petroleum asphalt roofing products at 4.8 million short tons in 1975 were only nominally below the 1974 results. Sales of such as asphalt cements and fluxes dropped 12.4% to 22.0 million short tons in 1975 from 25.1 million short tons in 1974.[7] Comparisons for 1974 and 1975 are also shown in table 39.

Production of asphalt also declined from 29.9 million to 26.2 million short tons, or 12.3%. With demand down, stocks increased 6.7% in 1975 (table 40).

Domestic demand for road oil in 1975 totaled 991,000 short tons, 20.8% less than in 1974 (table 40). Production declined slightly, but with demand reduced, inven tories increased again in 1975. Trends in demand for asphalt and road oil over the 5 year span 1971–1975 are also available in Table 40.

---

[7] U.S. Bureau of Mines. Sales of Asphalt in 1975. Mineral Industry Surveys, July 19, 1976, pp. 6.

Still Gas.—Still gas is a mixture of extremely low-temperature-boiling hydrocarbons produced during the distillation of crude oil and may be used as refinery fuel and/or as a petrochemical feedstock. During 1975, refineries used 175.4 million barrels of still gas as fuel, a nominal decrease from the 175.7 million barrels consumed in 1974.[8] Consumption of still gas as a petrochemical feedstock increased 9%, to 15.7 million barrels from 14.4 million barrels in 1974, and the uptrend continued in 1976.

Miscellaneous Finished Oils.—The petroleum industry produces a variety of miscellaneous products that are sold directly to consumers or in bulk to specialty companies, that package and distribute them under various trade names. Included in this category would be absorption oils, specialty oils such as hydraulic and insulating oils, medicinal oils, rust preventives, sand face, spray oils, and others. Also, synthetic natural gas (SNG) feedstock is included in this grouping. Production of miscellaneous finished oils in 1975 was about 32.2 million barrels, a gain of 27.6% over the 25.2 million barrels produced in 1974. Production of absorption oils increased nearly 29%, but the production of "other products," which includes SNG feedstocks, increased nearly threefold, from 3.8 million barrels in 1974 to 11.1 million in 1975 (table 42).

Unfinished Oils.—Unfinished oils are oils that have been partly refined and will be further processed by refiners; examples are unfinished naphtha, gas oil, virgin- or straight-run naphtha, topped crude, and cracking stocks. The rerun (net of unfinished oils) represents the receipts of domestic or foreign oil plus or minus changes in stocks.

TRANSPORTATION AND DISTRIBUTION

INTERDISTRICT MOVEMENTS

A transportation system comprised of pipelines, tankers, barges, tank cars, and to a lesser degree, tank trucks moves crude petroleum to refineries for processing. Refineries received 67.3% of their crude oil requirements by pipeline, 30.9% by water, and 1.8% by tank cars and trucks in 1975 (table 43).

Data collected on receipts of domestic and foreign crude petroleum at refineries in the United States show receipts from local production (intrastate), receipts from other States (interstate), and receipts of imported crude. These data, by method of transportation, indicate the final receipts by water, pipeline, tank car, and truck. Receipts of domestic crude by water usually are moved by pipeline from the point of production to the point of water shipment.

Refinery receipts of crude oil carried by tankers and barges totaled 1,406 million barrels, or nearly 3.9 million bpd in 1975. Some 78% of receipts by water was of foreign origin in 1975 compared with 72% in 1974. In 1971, foreign accounted for 37%. A 5-year series of receipts is shown in table 43; details on interdistrict movements by tanker and barge are given in tables 44 and 45.

The 17 States comprising PAD district I accounted for 36.3% of domestic product demand. Foreign oil accounted for 88% of refinery output in district I. Of the remaining 12% some 152,200 bpd was received primarily from district III. In district III, domestic oil made up 78% of crude oil input to refineries. In 1975, 42% of crude input to refineries in the entire United States was in district III. Output of refined product in district III exceeded demand by a wide margin; hence, the extensive movement from district III to other districts. The transportation of petroleum products by months by pipeline between PAD districts is shown in table 46. During 1975, the pipeline movement of motor gasoline from district III to district I averaged 968,000 bpd; during 1974, it averaged 880,000 bpd, a 10% increase.

Refined products produced at refineries in PAD district V in 1975 represented 91% of the domestic product demand for that district. Domestic crude oil produced primarily in California supplied 56% of refinery input, and of the 44% of oil imported one-third originated in Indonesia and nearly one-third came from the Middle East. Canada was an important supplier of crude oil for district V, particularly for those refineries in the Puget Sound area of Washington. The phaseout, however, of crude oil exports to the United States, which was enacted by the Canadian National Energy Board (NEB) in 1973, has caused sharp reductions in exports to the United States, from about 242,000 bpd in 1973 to some 163,000 bpd in 1975. Under the original NEB formula, crude oil exports to the United States would have been completely phased out by the end of 1981, but with the Sarnia-Montreal pipeline becoming operational there is a strong likelihood that Canadian oil exports to the United States will phase out by the late 1970's except for heavy crude oils. A similar action has been taken by NEB on natural gas exports to the United States, which are expected to end by 1984.

---

[8] U.S. Bureau of Mines. Crude Petroleum, Petroleum Products, and Natural Gas Liquids, Mineral Industry Survey, April 1976 issue, released Aug. 8, 1975, 30 pp.

There are, however, a number of new sources of oil and these could more than supply sufficient crude oil for needs of refineries in PAD district V and, at the same time, provide an excess to meet, in part at least, crude oil needs in the Midwest PAD district II and perhaps PAD district III. These are (1) Alaskan oil, (2) oil from Naval Petroleum Reserve No. 1 (NRPNO1) at Elk Hills, Calif., and (3) the offshore fields in the Santa Barbara Channel. Alaskan oil from the North Slope (Prudhoe Bay) is expected to start moving south through the Trans Alaska Pipeline to Valdez for tanker shipment to the west coast in August 1977. In NPRNO1, extensive drilling and development began in mid–1976, as directed in Public Law 94–258 enacted April 1976. The Canadian crude oil export phaseout is also having a drastic impact on "Northern Tier" refineries.

PIPELINES

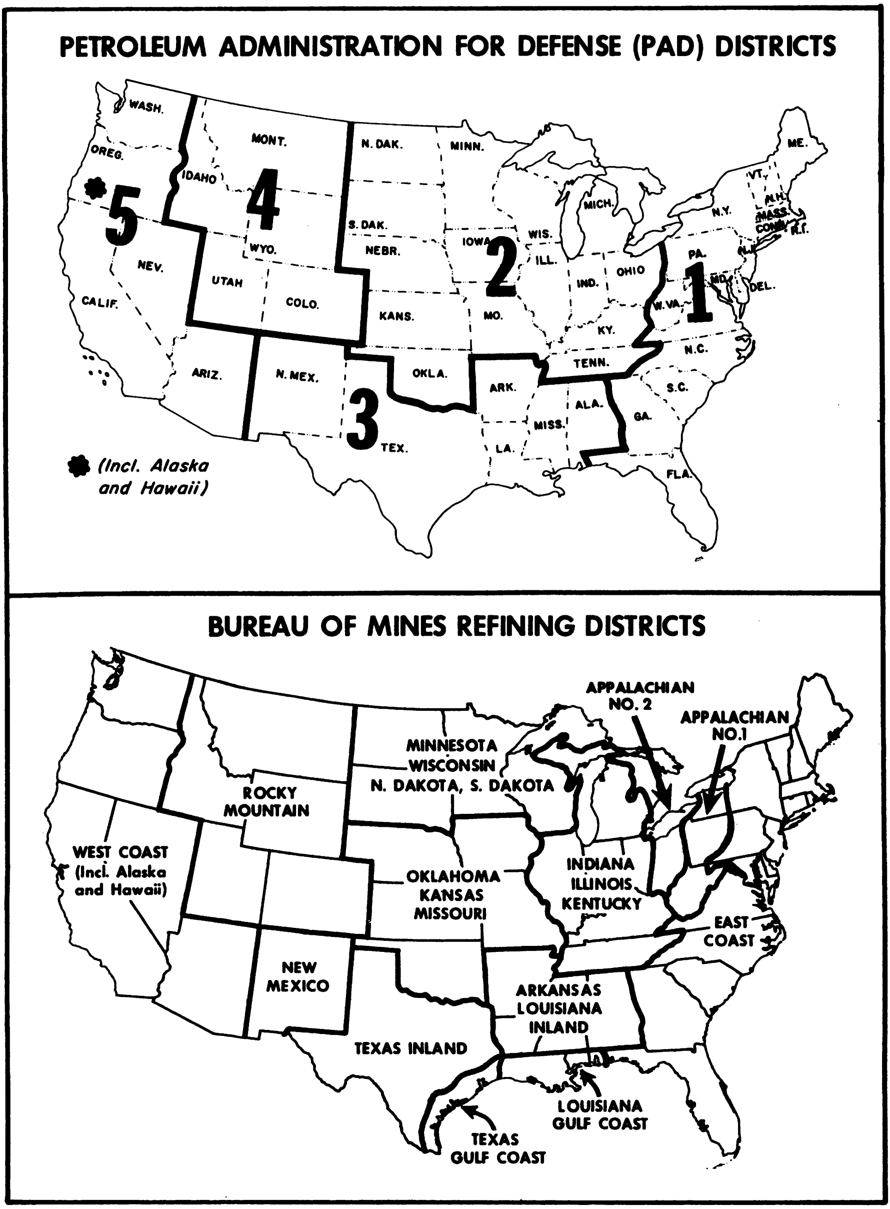
Crude oil pipelines delivered 3,060 million barrels, or 8.4 million bpd, to refineries in 1975, a decrease of 2% from the 8.6 million bpd in 1974 (table 43). Petroleum product pipelines delivered 3,272.2 million barrels, or an average of 8,965,000 bpd in 1975, compared with 3,225.2 million barrels, or 8,836,000 bpd, in 1974. Transportation by pipeline of petroleum products between PAD districts is shown in table 46. Transportation and stocks in lines and working tanks is available in table 49; tariff rates appear in table 48.

RAIL, TANK TRUCK, BARGE, AND TANKERS

The annual study of the Association of Oil Pipelines estimated that the total tonnage of crude oil and petroleum products carried was 1,874 million short tons in 1974. Of this total, 47% was transported by pipelines, 22% by water carriers, 29% by motor carriers, and 2% by railroads. On an overall basis, volumes transported in 1974 were 4% greater than those in 1972. Petroleum products accounted for 67% of the volume transported.

Product pipelines transport only the light products such as gasoline, light fuel oils, heating oils, LPG, kerosine, and jet fuel. These lines transported 1,253.5 million short tons, or 33.5% of the total. Motor carriers transported some 482 million short tons, or 38.45% of the petroleum products carried. In terms of billions of ton-miles, the total aggregated 489.6, of which 41.9% was transported by pipelines, 49.8% by water carriers, 5.4% by motor carriers, and 2.9% by railroads. Total crude petroleum carried in domestic transportation, was 356.8 billion ton-miles in 1974. Pipelines accounted for 84.4%, water carriers 14.8% and motor carriers and railroads 0.8%.

Deepwater Ports.—A tanker voyage from the Middle East to the U.S. east coast involves a 24,000-mile round trip, and use of very large crude carriers (VLCC's) could reduce transportaion costs markedly if deepwater ports were available. Many tankers in use today are VLCC's, and virtually all of these ships are unable to enter ports with a depth under 75 feet. At present, there are no United States ports capable of accommodating VLCC's with capacities greater than 200,000 deadweight tons (dwt). The deepest ports in the United States are on the west coast and can handle tankers up to 150,000 dwt. Most harbors in the United States are limited to ships with capacities ranging from 40,000 to 70,000 dwt.



PETROLEUM ADMINISTRATION FOR DEFENSE (PAD) DISTRICTS

BUREAU OF MINES REFINING DISTRICTS

Figure 5.—Maps of Petroleum Administration for Defense (PAD) districts and Bureau of Mines refining districts.

The Deepwater Port Act of 1974, signed by the President, provided for licensing and regulation of deepwater ports. The Secretary of Transportation is empowered to grant licenses for ownership, construction, and operation of deepwater-port facilities. At the same time, a Governor of an adjacent State located within 15 miles of a deepwater port or connected directly by pipeline to a deepwater port could veto the project.

Two corporations are planning to construct two deepwater ports—one 31 miles off the Louisiana coast at Grand Isle in water over 100 feet deep in the Gulf of Mexico, and the other off the Texas coast. At the Louisiana Offshore Oil Port (LOOP), the firm proposes to store imported oil in the Clovelly salt dome near Galliano, La. Proposed storage capacity of this facility is expected to be about 56 million barrels of oil. Seadock would be the second deepwater terminal, and it is proposed that it be constructed off the upper Texas gulf coast 25 miles south of Freeport. Storage facilities for Seadock will be located 5 miles inland and will consist of 28 tanks with a storage capacity of 22.5 million barrels.

Both of these applications are being considered by the U.S. Coast Guard, the agency authorized to review and issue permits and to monitor any deepwater terminals. If the permits are granted by mid–1977, the two terminals are expected to be on-line by 1980.

Oil off-loaded at such terminals would be transported to shore facilities by pipeline, thereby reducing the need to transfer oil cargoes from VLCC's to smaller vessels for transport to conventional terminals or refineries.

TANKER RATES

World tanker charter rates, after peaking late in 1973, have been in a downtrend. From $2.02 per barrel, charters in December 1973 for 34° crude oil for Large Range 2 tankers (80,000 to 159,999 dwt) dropped nearly 40% by December 1974 to $1.21 per barrel, for cargoes destined from Ras Tanura to New York via the Cape of Good Hope. Rates later firmed up, and at the end of 1975 were about $1.26 per barrel. Charters, same destination, for vessels of 16,000 to 24,999 dwt (classified as "General Purpose" tankers), dropped over the same 1973–74 interval from $3.23 per barrel to $2.63 per barrel. By yearend 1975, the rate for the smaller tankers, however, had rebounded to $2.90 per barrel. An oversaturation in tanker supply, particularly larger size tankers, has helped to weaken tanker rates. It should be noted, however, that average tanker charter rates move slowly since they include charters that run about 3 years. Also, much of the shipping moves in company-owned vessels.

STOCKS

Petroleum products stocks have been increasing steadily after reaching a low of 866.9 million barrels in February 1973. This was the lowest inventory position since February 1968 and close to stock levels during the 1967 Arab-Israeli conflict, which cut off imports from the Mideast. By yearend 1975, stocks of all oils had recovered to 1,133 million barrels, an increase of 60 million barrels over the end of 1974 as shown in table 49. Stocks of refined products were 52.8 million barrels higher at yearend 1975. Crude oil stocks, which shrank from 279.5 million barrels in May 1972 to a 7-year low of 235.4 million barrels in February 1973, climbed to a new record of 281.9 million by April of 1975. Stocks declined seasonally and at yearend 1975 aggregated 271.4 million barrels, a 6.3-million-barrel increase over the stock position of a year earlier.

STORAGE

The Arab Oil Embargo during the last quarter of 1973 and the first quarter of 1974 had a severe impact on the supply of oil needed to meet domestic demands. In an effort to diminish in the future the vulnerability of the United States to the effects of a severe oil supply interruption and to provide limited protection from the short-term consequences, Congress enacted legislation to establish a Strategic Petroleum Reserve (SPR) in Title I, Part B of the EPCA.

Under the initial phase of the SPR, referred to as the Early Storage Reserve (ESR), 150 million barrels of oil will be stored by 1978. Of the different types of storage facilities, existing solution-mined salt dome cavities are among the most attractive for petroleum storage because of the relative low cost of bulk storage and the extreme geological stability of the rock salt masses.

Under the EPCA the FEA is directed to pick the ESR phases of the program. Initially the FEA selected the eight sites listed below. From these, three will be finally selected for the ESR. Candidate sites are Bryan Mound, Brazoria County, Tex.; Cote Blanche Island mine, St. Mary's Parish, La.; Weeks Island mine, Iberia Parish, La.; West Hackberry Salt Dome, Cameron Parish, La.; Bayou Choctaw Dome, Iberville Parish, La.; Kleer salt mine, Van Zandt County, Tex.; and limestone mines near Central Rock, Ky., and Ironton, Ohio. Filling of storage will start about August 1977, at the rate of 40,000 to 50,000 bpd.

PRICES

Crude Oil.—The increase of the host countries' shares in oil participation from 25% to 60%, and in some countries complete nationalization, coupled with sharp increases in prices adopted by the Organization of Petroleum Exporting Countries (OPEC) in 1973 and 1974, caused consternation in oil-consuming nations throughout the world. These actions are discussed in the World Review section of this chapter. The uptrend in prices continued in 1974, but with economic recession worldwide and crude oil a glut on world markets, the climb in prices had been arrested as of mid-1975. Prices picked up momentum in October 1975, however, with a 10% increase announced by OPEC.

A large part of crude oil obtained from foreign countries is equity oil; that is, oil produced and owned by companies that had obtained concessions from host governments. In return, the companies were required to pay both a royalty and a tax on oil produced. The aggregate of tax-royalty and the cost to produce oil represented the total cost of equity oil and was termed "tax-paid cost." The royalty and tax were based on a posted price that was initially established by negotiation between the host country and the oil-producing company. More recently, however, the host government alone has established the posted price.

Prices continued to rise in 1975. The posted price for Arabian light crude oil as of October 1975 was $12.38 per barrel.

The average value of domestic crude oil at the wellhead, which was $3.39 per barrel in 1971, and 1972, increased to $3.89 in 1973, $6.74 in 1974, and $7.56 in 1975. These increases were the result of an effort to stimulate production of domestic crude oil by the Cost of Living Council (CLC) which on August 17, 1973, enacted a two-tier pricing system under phase 4 oil regulations. The system released from ceiling prices "new oil" (oil produced above 1972 levels) and made an adjustment for the remainder of current production. The price of new oil produced, which was not covered by the price ceiling, rose steadily to market levels. The ceiling price for domestic crude was about $1 per barrel below the world price at the time phase 4 rules were issued on August 17. Since then, however, world prices have increased sharply and so have prices for new or exempt oil; that is, oil exempt from price controls.

The price-regulating function of CLC was absorbed by FEA in March 1974, and FEA took over this work in May 1974. Between January and December 1974 the price per barrel rose from $9.82 to $11.08. The price of old oil rose from $3.90 per barrel in August 1973 to $5.03 (revised) in December. FEA revised its calculations so that the price of old oil was reduced from $5.25 per barrel to $5.03 per barrel. Shown on the next page are prices per barrel wellhead for old and new crude petroleum for the last month of each quarter in 1974 and 1975. Data through June 1976 are also shown to illustrate the impact of EPCA after January 1976. Domestic crude petroleum prices per barrel, as shown on the next page, have climbed 11.6% from a 1974 average composite price of $6.87 to a 1975 average of $7.67. Likewise, prices refiners must pay for crude oil, both domestic and foreign, have also risen due to refiner's acquisition costs. This cost is the price paid by refiners for domestic crude petroleum, unfinished oils and natural gas liquids and includes transportation costs from the wellhead to the refinery.

	Old	New	Domestic average
1974:			
March	$5.03	$9.88	$6.77
June	5.03	9.95	6.85
September	5.03	10.10	6.70
December	5.03	11.08	7.09
Average	5.03	10.13	6.87
1975:			
March	5.03	11.47	7.57
June	5.03	11.73	7.49
September	5.04	12.46	7.75
December	5.03	12.95	7.93
Average	5.03	12.03	7.67
1976:			
January	5.02	12.99	8.63
February	5.07	11.44	7.82
March	5.07	11.39	7.80
April	5.07	11.52	7.86
May	5.13	11.59	7.98
June	5.15	11.60	7.99

The following tabulation shows refiner's acquisition cost per barrel for imported oil, domestic oil, and a composite of both as maintained by FEA:

	Domestic	Imported	Composite
1974:			
March	$7.05	$12.73	$8.68
June	7.20	13.06	9.45
September	7.18	12.53	9.13
December	7.39	12.82	9.28
Average[r]	7.18	12.52	9.07
1975:			
March	8.38	13.28	9.91
June	8.33	14.15	10.33
September	8.49	14.04	10.79
December	8.66	14.81	10.98
Average	8.39	13.93	10.38
1976:			
January	9.14	13.27	10.76
February	8.67	13.26	10.54
March	8.48	13.51	10.44
April	8.66	13.39	10.63
May	8.56	13.20	10.53
June[p]	8.59	13.47	10.88

[p] Preliminary. [r] Revised.

A composite of refiner's acquisition costs of imported and domestic crude was $3.85 per barrel in May 1973. By December 1975, the price was $10.98 per barrel, nearly a threefold increase. The rise was due primarily to the increase in the cost of imported oil. The refiner's acquisition cost for imported oil rose from $3.92 per barrel in May 1973 to $14.81 per barrel by December 1975, nearly a fourfold increase.

Section 401 of EPCA amended the EPAA by adding a new section 8, which sets forth crude oil pricing policy. This policy required the President to adopt implementory regulations designed to result in the maximum weighted average first sale price during the month of February 1976 of $7.66 per barrel as stipulated in the EPCA. In subsequent months the EPCA permits adjustments in the first sale price of domestic crude to take into account the impact of inflation as a production incentive. For example, if current production from a property exceeds 1972 base production control levels (BPCL) for the property, the excess production qualifies under the new regulations as "new" crude oil.

Entitlements.—The FEA continued its entitlements system under the Old Oil Allocation Program (CFR 211.67). Every refiner had to have an entitlement to process a barrel of old crude oil as a percentage of total crude processed (that is, the total runs to stills) of old oil, imported oil, and domestic exempted oil. Each month, FEA calculates the amount of old oil produced as a percentage of total crude oil processed. If, for example, the old-oil ratio was 40% and a refiner's old-oil ratio was 60%, this refiner would have to buy entitlements equal to 20% at prices set by FEA from those refiners with less than 40%. An entitlement purchased at $5.00 would entitle the purchaser to process 1 barrel of old oil at about $5.03 per barrel, so that the effective cost would be about $10.03 per barrel for the 20% over the old-oil ratio.

Data on prices of selected crude oils and products are given in tables 55 and 57.

In the United States, gasoline outweighs all other products in terms of volume produced and relative importance in the refinery mix. Prices of gasoline have continued upward. The average service station price of regular-grade gasoline (including taxes) has risen from 42.26 cents per gallon as of December 1, 1973, to 53.15 cents per gallon on December 1, 1974, and to 59.42 cents per gallon on December 1, 1975, according to Platt's Oil Price Handbook and Oilmanac, 1975 edition.

Shown in the following tabulation (in dollars per 100 gallons) are some comparisons in selected cities of prices of No. 2 home-heating oil between December 1972 and January 1976. These intervals indicate the impact of the passthrough policy on retail prices. Between January 1974 and January 1976 the U.S. average rose 26% from $32.89 to $41.46 per 100 gallons.

Standard metropolitan statistical area	December 1972	December 1973	January 1974	January 1975	January 1976
U.S. average	$19.72	$22.76	$32.89	$37.84	$41.46
Baltimore	19.33	26.64	31.18	36.60	41.02
Boston	20.40	30.44	32.90	40.06	42.49
Chicago–northwestern Indiana	18.65	27.01	31.66	33.96	43.73
Detroit	18.62	25.14	30.35	35.75	39.68
Milwaukee	18.93	27.85	31.23	36.58	40.07
Minneapolis–St. Paul	18.06	26.42	34.74	35.72	40.13
New York and northeastern New Jersey	20.40	33.41	36.90	40.04	34.82
Philadelphia	19.23	26.27	21.30	37.96	43.52
St. Louis	19.49	26.53	33.72	37.51	40.98
Washington, D.C	19.78	29.95	33.30	40.82	41.99
Seattle	22.17	27.28	33.50	38.20	44.93

Residual Fuel Oil Prices.—The price of Bunker "C" fuel oil at New York Harbor has been in an uptrend since 1972; from $3.45 per barrel at the end of 1972, to $5.42 per barrel by December 1973. By December 1975, the price had more than doubled. The trend of Bunker "C" prices for 1964–75, inclusive, is shown in figure 7.

Unlike the use of Bunker "C" fuel, use of No. 6 residual fuel oil is restricted to 0.3% sulfur in many communities along the eastern seaboard. New York City is an example. The average price per barrel for No. 6 fuel oil in New York Harbor market since 1971 follows:

1971	$ 4.87
1972	4.66
1973	5.99
1974	14.11
1975	13.39

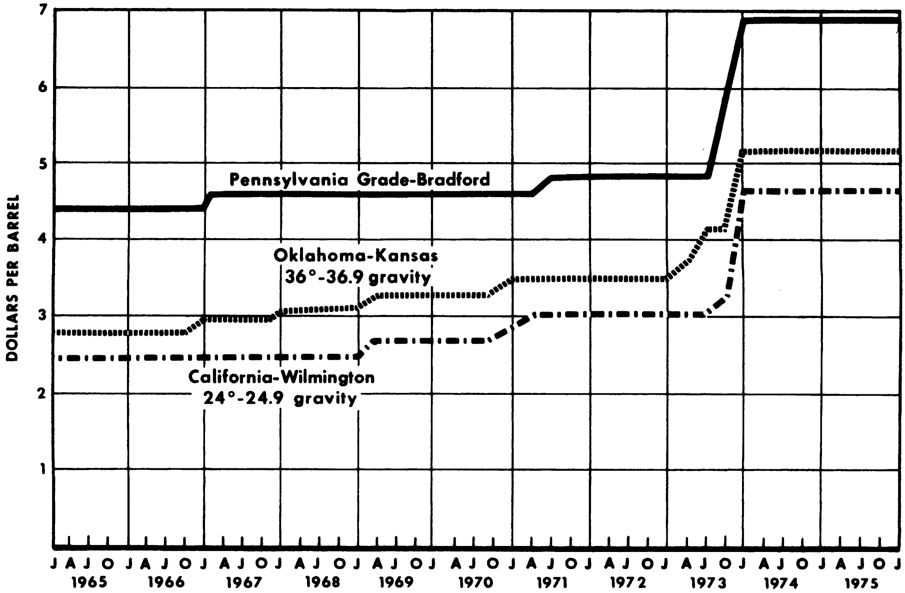

Figure 6.—Posted prices of selected grades of crude petroleum.

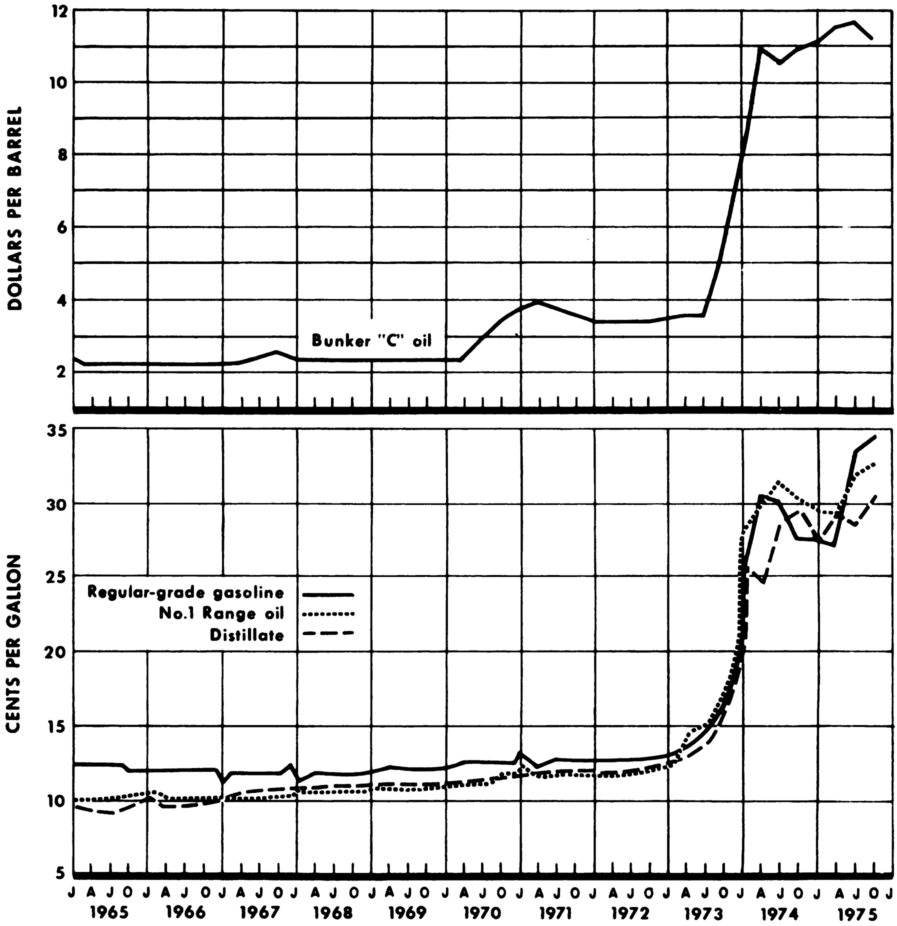

Figure 7.—Quarterly prices of bunker "C" and No. 2 distillate fuel at New York Harbor, No. 1 range oil at Chicago district, and regular-grade gasoline at refineries in Oklahoma.

FOREIGN TRADE

Exports.—Refined products exports declined 4.1 million barrels to 76.4 million barrels in 1975 as reductions in exports of coke, lubricating oils, and other products more than offset increases in residual fuel oils and petrochemical feedstocks. Exports of petroleum coke to Japan and West Germany declined sharply but exports to the Netherlands rose 51% to 7.1 million barrels. Exports by product and destination in 1974 and 1975 are shown in table 59.

Imports.—Imports of crude petroleum and refined products decreased a nominal 1.4% to about 2.2 billion barrels, or 6 million bpd, in 1975. Imports of crude in 1975 were 18% above those of 1974, but this increase failed to offset the 27% drop in the imports of petroleum products. Increasing sharply were crude imports from Venezuela, Saudi Arabia, Libya, and Nigeria. Also, imports from Mexico jumped from about 600,000 barrels in 1974 to more than 25 million barrels in 1975 (table 61). Conversely, imports from Iran decreased nearly 40%, from 463,000 bpd in 1974 to 278,000 bpd in 1975. As a result of Canada's planned cutback in crude oil exports to the United States, imports from that country dropped from 791,000 bpd in 1974 to 600,500 bpd or 24%.

Nigeria was the largest supplier of crude oil to the United States. Imports from that country averaged nearly 746,000 bpd in 1975, a 7% increase over the amount received in 1974. Imports of crude from Africa in 1975 averaged 1.3 million bpd, which was 19% larger than crude imports from the Middle East.

Imports of refined products in 1975 aggregated 1.9 million bpd, which was 27% below the 2.6 million bpd in 1974. Similar to the pattern of 1974, most of the decrease in 1975 was in the imports of residual fuel oil, distillate fuel oil, and kerosine-type jet fuel. In addition, imports of motor gasoline decreased almost 10% so that the drop in the four products aggregated 578,707 bpd, or 81% of the total decline in product imports which totaled 715,000 bpd. Moreover, of the decline of 578,707 bpd, residual fuel oil accounted for 392,433 bpd, or nearly 68%. Part of this decline in residual fuel oil imports reflects the reduced demand of 7.8% in 1975, but even more significant is the 15% increase in production of residual fuel oil by domestic refineries—from 1,070,000 bpd in 1974 to 1,235,000 bpd in 1975. Production of residual fuel oil by domestic refineries has not exceeded imports of that product since 1963. Production in the low-sulfur range (1.0% or less sulfur content by weight) increased 8.8%, averaging 616,000 bpd in 1975 compared with 566,000 bpd in 1974. Imports of low-sulfur fuel oils averaged 681,000 bpd, or nearly 24% below the 894,000 bpd in 1974. Comparisons of imports in 1975 and 1974 by country and by product are shown in table 61.

NATIVE ASPHALT

Bituminous Limestone, Sandstone, and Gilsonite.—Natural rock asphalt and limestone rock asphalt were produced in Alabama, Missouri, and Texas and were used for road-building material. Gilsonite was produced in Utah. The total production of native asphalts and related bitumens in 1975 was 1,901,715 short tons with a value of $19,838,000.

WORLD REVIEW

The world recession persisted throughout 1975 as petroleum-consuming nations attempted to adjust to the economic burdens resulting from a fourfold increase in crude oil prices by OPEC member nations. In view of reduced consumption following price increases during 1973–74 no further price increases were adopted by OPEC for the first 10 months of 1975.

The September meeting of OPEC, however, resulted in a 10% increase in the posted price of Arabian "marker" crude (34° API), thus raising the price from $11.25 to $12.38 per barrel effective October 1, 1975. Prices of most other OPEC crudes were, however, increased by less than 10%. For example, the price of Iranian light crude (34° API) was increased by 8.9%, Arabian heavy crude (27° API) by 8.5%, Qatar light crude (40° API) by 6.0%, and Indonesian Minas crude (35° API) by only 1.6%. Variable price increases were accepted within the OPEC structure by adjusting low-sulfur, gravity escalation, and location-advantage premiums.

Government revenues of OPEC member nations totaled an estimated $93 billion in 1975, a 3% increase over 1974 revenues. Increased revenues were realized in spite of reduced exports. When calculated on a per-barrel basis, OPEC revenues averaged an increase of 11%. Decreased per-barrel revenues were reported only by OPEC's African member nations. Libyan per-barrel revenues declined by nearly 13%, Nigerian by 4%, and Algerian by 3%. Revenue decreases for the African OPEC nations resulted from progressive price trimming in an attempt to reverse export declines in early 1975.

Governments of many oil-producing nations continued programs of increased participation in oil industry activities within their borders. During 1975, Iraq nationalized the remaining interests of the Basrah Petroleum Co., bringing that nation's petroleum industry under total Government control. Negotiations for total Government takeover of Kuwait Oil Co. were completed with National Assembly ratification anticipated early in 1976. December 31, 1975, marked the close of foreign company ownership in Venezuela's petroleum operations. State participation in petroleum operations remained at 60% in Saudi Arabia and in Qatar; however, both Governments anticipate a 100% takeover in 1976 with Qatar negotiating for a nationalization date retroactive to December 1974.

Government participation in other OPEC countries for the most part maintained a status quo. The Iranian Government, represented by the National Iranian Oil Co. (NIOC), exercised total control of onshore production representing more than 90% of that nation's output. Production from Iran's offshore wells is conducted by private companies in partnership with NIOC. Algeria's state-owned company Société Nationale pour la Recherche, la Production, le Transport, la Transformation, et la Commercialisation des Hydrocarbures (SONATRACH) controls about 80% of the total petroleum production. A more liberal trend may be indicated by newly negotiated exploration-production contracts which obligate SONATRACH to reimburse private companies up to 15% of exploration costs on commercial discoveries, provide 51% of development costs, and participate in no more than 60% of production. Libya unilaterally announced a 51% takeover of petroleum operations in 1973. Any challenge to the government action resulted in total takeover by the Libyan National Oil Co. Indonesian operators recovered costs from 35% to 40% of production with remaining production shared on a 65% and 35% basis in favor of the state-owned petroleum company Pertamina. The respective Governments of Abu Dhabi, Oman, and Bahrain enjoyed a 60% participation in petroleum production operations within their boundaries. Nigerian Government participation continued on a 55% to 45% basis. Government participation in Ecuador remained at 25%. Gabon, which joined OPEC in 1975, as yet reported no Government participation in petroleum production.

The International Energy Agency (IEA) formed in late 1974 by oil-consuming nations[9] for the purpose of sharing energy resources in the event of another embargo and to promote international cooperation in developing alternative energy sources was joined by Norway and New Zealand in 1975, bringing the total number of participating countries to 18. During the year member nations agreed to increase their emergency petroleum stockpile reserve from a 60- to a 70-day supply by 1976, with a 90-day stockpile reserve set as a goal for 1980. Among the activities of the IEA in 1975 was the creation of an Industry Advisory Board[10] to provide advice on emergency petroleum sharing and to assure efficient execution of any emergency allocation program. Throughout 1975 extensive negotiations were conducted to establish a long-term cooperation agreement supporting a minimum price below which participating countries will not allow imported oil to be sold within their domestic economies. Negotiations neared a successful conclusion by yearend.

Production.—World crude oil and field condensate production dropped to 53.4 million bpd in 1975, representing a decline of 5% from 1974 production levels. Leading producers included the U.S.S.R. with a reported production of crude oil and field condensate averaging 9.9 million bpd, the United States averaging 8.4 million bpd, and Saudi Arabia averaging 6.8 million bpd.

Production from the 13 member nations of OPEC approached 27.2 million bpd, a reduction of 3.5 million bpd from 1974 output levels. OPEC production capacity is estimated at 37 million bpd. For the most part, production cutbacks have been maintained to support higher price levels.

(California), Standard Oil Co. (Indiana), Den Norske Stats Oljeselskap AS, Texaco Europe, Texaco Inc., Union Oil Co. of California, Veba-Chemie, A.G.

Production from non-OPEC nations averaged 26.2 million bpd in 1975 representing a production decline of 0.7 million bpd from the previous year's output levels.

Production declines were most evident in North America with U.S. production down by more than 0.4 million bpd and Canadian production down by nearly 0.3 million bpd. Any production growth among non-OPEC producers in the immediate future will stem from Mexico, the North Sea, and the Alaskan North Slope.

Approximately 1 out of every 7 barrels of oil produced in 1975 was obtained from an offshore field. Leading offshore producers were Saudi Arabia and the United States, each producing about 1.4 million bpd from offshore fields. Other major offshore producers were the United Arab Emirates, producing 0.6 million bpd, and Iran, producing in excess of 0.3 million bpd. Development activity in the North Sea continued with two fields in the British zone entering production in 1975. By 1976 production from the North Sea should average about 500,000 bpd.

Crude Oil Movements.—Crude oil constitutes about 80% of all Western European petroleum imports, nearly 90% of Japanese petroleum imports, and nearly 70% of petroleum imports of the United States. Crude oil movement to these major markets totaled more than 20.2 million bpd. Nearly two-thirds of these imports were obtained from the Middle East. Excluding intra-European shipments, Western European total crude imports averaged 11.6 million bpd with the Middle East supplying 8.5 million. Japanese crude imports from the People's Republic of China continued to grow, averaging nearly 158,000 bpd in 1975. The United States imported an average of 4.1 million bpd of crude oil. The leading suppliers to the United States were Nigeria, averaging 746,000 bpd; Saudi Arabia, 701,000 bpd; and Canada, 600,000 bpd.

Transportation.—A total of 326 new vessels representing a combined capacity of 44.3 million dwt was added to the world tanker fleet, while scrappings, conversions, and losses reduced the fleet by 291 vessels representing a combined capacity of 8.8 million dwt; at yearend 1975 the world tanker fleet comprised 3,674 vessels having a combined capacity of 291.4 million dwt. As a result of the reduced world demand for petroleum, surplus tanker capacity reached an estimated 115 million dwt at yearend.

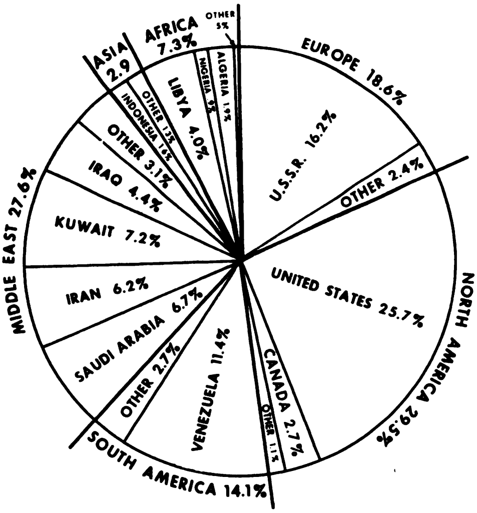
More than 30.7% of the world tanker fleet sails under the Liberian flag, 11.2% under the flag of the United Kingdom, and 10.9% under the Japanese flag. Tankers between 200,000 and 285,000 dwt constitute 40% of the total tanker fleet; tankers between 125,000 and 200,000 dwt constitute 10%; while tankers between 65,000 and 125,000 dwt constitute 20%.

Voyages from the Middle East occupied an estimated 75% of the oceangoing fleet. Voyages from the Middle East to Europe alone occupied about 50% of the total oceangoing fleet. During 1975, tanker movements on the Mediterranean Sea were diminished with the closure of the Tapline export terminal at Sidon, Lebanon. Reduced tanker rates afforded a savings of $1.50 per barrel on crude shipped to Europe via the Persian Gulf as opposed to the more expensive overland route to the Mediterranean Sea. Tanker traffic in the Mediterranean Sea, however, did increase in the last half of 1975 as a result of the reopening of the Suez Canal in June. Draft limitations of the canal permit passage of laden tanker of no more than 40,000 dwt. Laden tankers represented only 6% of the Suez Canal traffic in 1975. The Suez Canal can accommodate tankers of up to 100,000-dwt capacity if the vessel is passing through the canal in ballast. Tankers returning to the Persian Gulf in ballast represented 20% of the Suez Canal traffic in 1975.

Most United States east and gulf coast ports can only accommodate tankers of 70,000 dwt or less. Without lightering and transshipment facilities, importers could not benefit from the economic advantages realized in utilizing very large crude carriers for long-distance hauls. Transshipment terminals are operating at Grand Bahama Island and at Curacão. At yearend, a transshipment terminal was nearing completion at Bonaire, Netherlands Antilles. The terminal will be in service early in 1976.

Refinery Capacity.—Total world crude refinery capacity was estimated at 71.8 million bpd at yearend 1975, an increase of

1965–11.1 Billion Barrels



1975–19.5 Billion Barrels

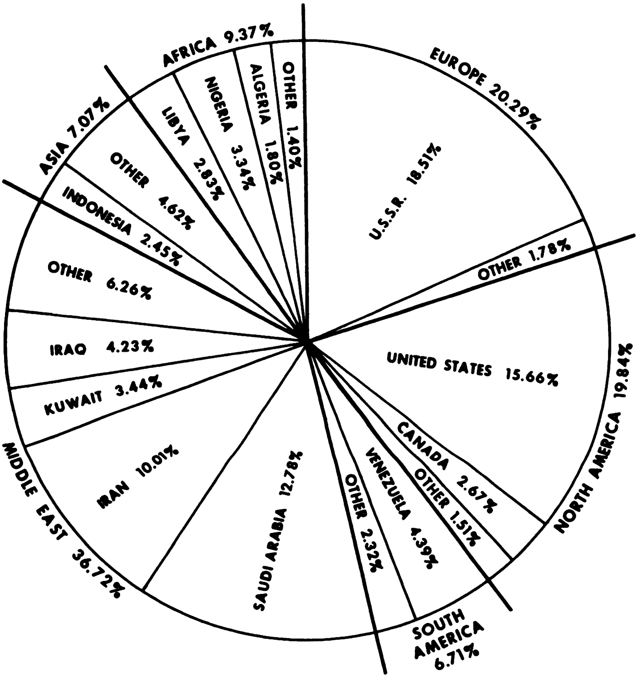


Figure 8.—World share of crude oil production in 1965 and 1975.

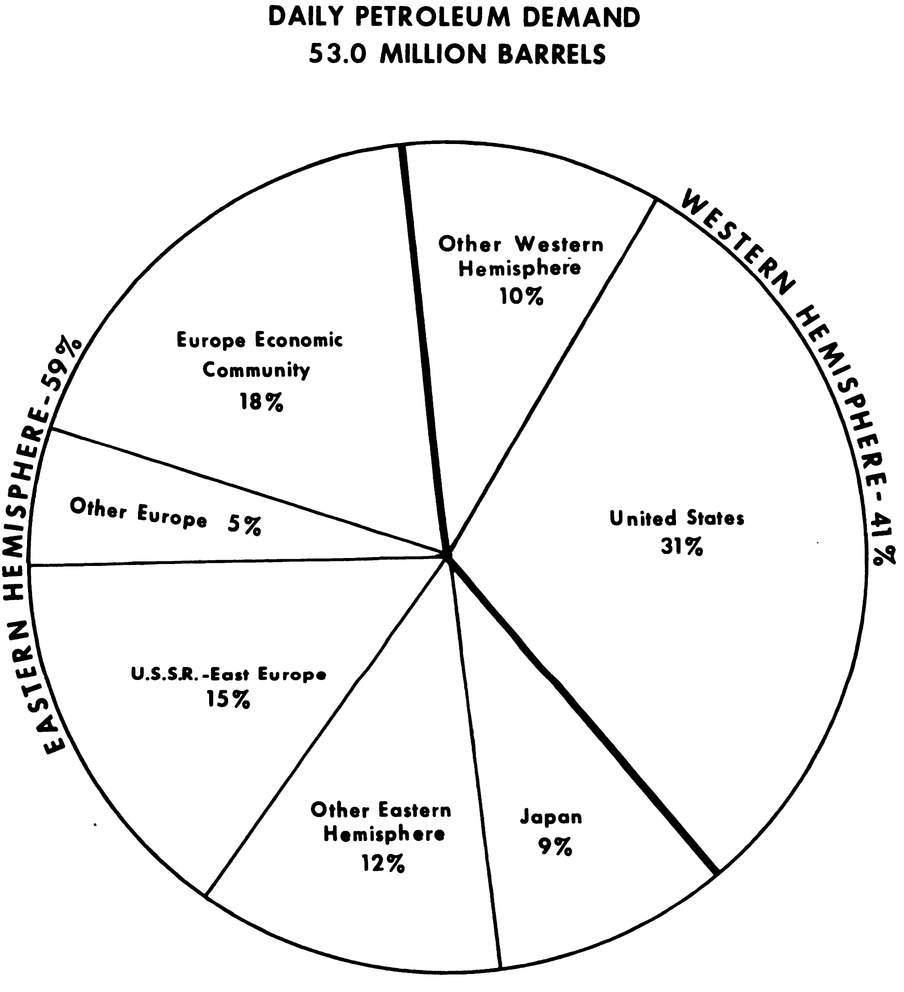

Figure 9.—World daily petroleum demand in 1975.

3.8 million bpd over 1974 levels. The Eastern Hemisphere with major refining centers in Western Europe, the U.S.S.R., and Japan accounted for nearly 65% of the total world refining capacity, or about 47 million bpd. As a result of reduced demand, most refineries operated well below capacity levels. In Western Europe crude oil and blendstock throughput represented only 60% of refining capacity. Japanese refiners operated at 80% capacity, and the U.S.S.R. refineries operated near capacity levels. Refining capacity in the Western Hemisphere totaled 24.8 million bpd; refining capacity of the United States was 15 million bpd, followed by Canada at 2 million bpd and Venezuela at nearly 1.5 million bpd.

Consumption.—World petroleum consumption declined to 53 million bpd in 1975 as a result of continued high prices. Consumption levels in major industrial areas continued to decline; Western European consumption was down to 12.2 million bpd, U.S. consumption was down to 16.3 million bpd, and Japanese consumption was down to 4.8 million bpd. Western European

consumption was reduced by 1.8 million bpd; U.S. consumption by 0.3 million bpd; and Japanese consumption by 0.8 million bpd compared with 1974 consumption levels.

Algeria.—The slowdown in exploration and development programs which resulted from the 1971 nationalization actions has been reversed. The Algerian state oil company, SONATRACH, contracted with nine foreign companies for exploration on more than 49,000 square miles of tracts covering both onshore and offshore areas.

Algerian production averaged 961,000 bpd in 1975; however, production plans call for an output of 1.3 million bpd by 1977 and 1.5 million bpd by 1980. Refining capacity in 1975 was reported at 120,000 bpd. Announced refinery expansion plans place capacity at 700,000 bpd by 1980. The largest refinery will be located at Skikda. It is scheduled for completion in 1979 at a 350,000-bpd-capacity. Algeria's petroleum product consumption projection for 1980 is less than 100,000 bpd affording 600,000 bpd of petroleum products for the export market.

China, People's Republic of.—Crude production approached an average of 1.6 million bpd in 1975, an increase of 20% over 1974 production. About 40% of China's total production is derived from the Taching field on the east coast. This field supplies most if not all of China's crude export, about 200,000 bpd in total, to markets in Japan, the Philippines, and Thailand; however, the wax content of Taching crude has decreased its marketability and future export patterns may be readjusted.

China's current refining capacity is estimated at over 1 million bpd. Refinery expansion programs balance proposed production programs which foresee output in a range of 2 to 2.4 million bpd by 1980.

Egypt.—Production increased by 57% to 231,000 bpd in 1975. Much of the production increase was attributed to the El Morgan field where a waterflood pressure maintenance project was underway, raising output from El Morgan to 80,000 bpd. Other significant producing fields include the July field, which yielded an average 35,000 bpd, and the Ramadan field which yielded an average of 25,000 bpd. At yearend 1975 the Sinai oilfields were returned to Egypt; the fields, which average 80,000 bpd, had been operated by Israel since the 1967 war. Production from the Sinai fields during Israeli occupation was estimated at well over 200 million barrels.

More than 30 companies have entered into exploration-production sharing contracts with the Egyptian General Petroleum Co. Several significant discoveries were reported in 1975, offering realistic support to the announced production goal of 1 million bpd by 1980.

Construction continued on the dual 42-inch pipeline connecting the Gulf of Suez to the Mediterranean Sea. Completion of the line was anticipated by 1976 at a cost of $400 million. Financing was shared by Egypt, Saudi Arabia, Kuwait, Qatar, and Abu Dhabi.

The Suez Canal was reopened in June. The draught of the canal is 38 feet placing severe limitations on use by laden tankers.

Indonesia.—The state petroleum and natural gas company, Pertamina, suffered serious liquidity problems in 1975, largely as a result of anticipating availability of long-term financing for approved projects when a recession economy offered only short-term financing. Revenues anticipated from petroleum exports were not realized and this further complicated Pertamina's credit status. In the face of reduced world demand, Indonesian production averaged 1.3 million bpd, well below its productive capacity of 1.7 million bpd. Higher premiums placed on Indonesian high-gravity, low sulfur crudes, and for proximity to Japanese ports had rendered Indonesian crude uncompetitive. With market realities in view, Indonesia adjusted crude oil prices in October far below the official 10% increase prescribed by OPEC. Minas crude was priced at $12.80 per barrel, representing an increase of only 1.6%. Furthermore, Indonesia reduced lesser quality crude prices by 4%, bringing Indonesian crudes more in line with Middle Eastern crudes delivered to markets in Japan.

The new pricing system resulted in increased production by November and December of an additional 50,000 bpd. Another measure to increase revenues was taken by raising the share of receipts from foreign companies on production-sharing contracts. Caltex, Indonesia's largest operator, producing over half the total crude output, agreed to cut profits and increase payments to the Government by $1.00 per barrel, adding $300 million to Indonesia's annual revenue. Readjustment of other production-sharing contracts was under consideration by yearend.

Iran.—Crude output was down by more than 11% from 1974 levels to an average of 5.3 million bpd as a result of reduced world demand. More than 91% of Iran's crude oil is produced from the Khuzestan oilfields onshore in southern Iran. Owned by the National Iranian Oil Co. and operated under a service contract by the Oil Service Co. of Iran, the Khuzestan Oil fields are under a production expansion program which includes an impressive gas injection program which should boost recovery of oil in place by 40% to 50% from a current rate of 20% to 30%. The project will utilize both associated and unassociated gas, requiring a total of 13 billion cubic feet per day. Productive capacity of the Khuzestan fields is close to 6 million bpd. The gas injection program will hopefully boost this capacity to 6.5 million bpd, a level which should be maintained for several years.

Iraq.—Crude production approached 2.3 million bpd, representing an increase of 15% over 1974 levels. A major factor in the increased production realized in 1975 was price readjustment.

The completion of a 412-mile, 42-inch pipeline between the Kirkuk and North Rumalia fields in 1975 was a most significant accomplishment for Iraq because it provided flexibility in marketing its crude via either Mediterranean or Persian Gulf ports. Formerly Kirkuk crude access to export markets was limited to a pipeline crossing Syria and Lebanon to reach Mediterranean terminals. The newly completed reverse-flow pipeline has an initial capacity of 500,000 bpd, and increases the pipelines' export capability. A 48-inch pipeline is under construction linking the North Rumalia field to Fao where submarine pipelines transport crude to a deep-water terminal about 26 miles out from the coast. The terminal is designed for two loading berths with capacity to load a total of 800,000 bpd. Eventual planned design could include six berths with a total loading capacity of 2.4 million bpd.

Libya.—Crude production averaged nearly 1.5 million bpd in 1975, a slight decrease from the 1974 level and a substantial decrease from the peak production level of 3.3 million bpd in 1970 before Government actions curtailed oil output.

The Libyan National Oil Corp. announced the discovery of a major offshore field in a concession operated by Elf-Aquitaine, but no further information was available at yearend. The Libyan National Oil Corp. also announced three discoveries in concession areas held by Occidental Petroleum Co. in the northwest Sirte basin area. Field development is linked with a production-sharing contract which affords Libya 81% of the production; the discovering company acquires 19%, free of taxes and royalty. Libya pays 81% of development costs; however, the payment is merely a loan which is to be repaid with interest over the field's productive period.

Nigeria.—Crude production was reduced by nearly 21% for an average of about 1.8 million bpd. The bulk of Nigeria's output is derived from Royal Dutch Shell and British Petroleum operations which yielded approximately 1.2 million bpd from 70 onshore oilfields.

Saudi Arabia.—Crude production capacity approaches 12 million bpd; however, production averaged about 7 million bpd owing to the reduction in world demand. More than half of Saudi's Arabia's production is derived from the Ghawar field, where production averaged 4.2 million bpd in 1975.

The Arabian American Oil Co. (Aramco) was the sole operator in Saudi Arabia. Government participation in Aramco was acquired in 1974 at 60%. Total Government ownership is anticipated by 1976 with Aramco providing operational personnel and technology.

Three new fields were discovered by Aramco in 1975. The offshore fields of Lawhah and Ribyan and the Dibdibah onshore field have augmented Saudi Arabian reserves by nearly 4.5 billion barrels.

U.S.S.R.—Production of crude oil and condensate averaged nearly 9.9 million bpd, an increase of 644,000 bpd over 1974 production levels. Most of the production increase was attributable to the Samotlar field in western Siberia where production averaged nearly 1.8 million bpd, as compared with more than 1.2 million bpd in 1974. The field's ultimate planned capacity of 2.4 million bpd should be reached by 1977. Production from other western Siberian fields averaged approximately 1.2

million bpd in 1975. Production from the Ural-Volga region was estimated at 3.5 million bpd. This region includes Tataria, where production was in excess of 2 million bpd. Other major producing areas in the region were Bashkiriya and Kuybyshev.

United Kingdom.—Production from the North Sea was realized in midyear when the Argyll field entered production. Production from the field averaged 35,000 bpd and was transported by tanker to the Isle of Grain refinery on the southwest coast of England. By October, the Forties field came onstream at 50,000 bpd. Production was delivered via pipeline to the Grangemouth refinery near Aberdeen, Scotland. Production from the Forties field is expected to reach 400,000 bpd by 1977, supplying approximately one-quarter of the United Kingdom's petroleum consumption requirements.

Venezuela.—Crude production dropped more than 21% below 1974 levels to 2.3 million bpd. Contributing factors to this decline were uncertainties associated with pending nationalization and Government-curtailed production. The bulk of Venezuela's output is derived from the Maracaibo onshore and offshore region. Other producing areas include Anzoátegui, Monagas, Guarico, and Barinas.

In 1975, Venezuela's exports of crude oil averaged nearly 1.5 million bpd and product exports averaged 0.6 million bpd, compared with 1.8 million bpd and 1.0 million bpd, respectively in 1974.

TECHNOLOGY

During 1975, new technology was developed for application in the exploration and drilling processes. Recent developments included (1) research on drill-bit design and deep-drilling effects, (2) mud system unitization and torque-reducing additives, (3) new tools for the control of blowouts and a system for detecting hydrocarbon and recovery of gas liquids, and (4) development of new offshore rig design and use of satellite communication systems.

The Division of Applied Technology of the Energy Research and Development Administration (ERDA) awarded the Sandia Laboratories of Albuquerque. N.M., $245,000 to study two drill-bit designs, which the laboratory proposed last year. The goal of this study is a design that will extend downhole life of the rotary bit before it must be pulled for replacement. If the extended-lift bit design is practical, appreciable savings in time needed for deep wells would make this type of bit worthwhile. The principle of the design is that a new cutting surface can be rotated into place when the cutting surface wears out, without pulling the drill string.[11]

Reed Tool Co. and Terra Tek, Inc., of Salt Lake City, have completed a full-scale installation capable of fully simulating downhole drilling conditions. The facility will mainly be used for testing full-scale rock bits at simulated depths of up to 30,000 feet and for research in geothermal and permafrost drilling.[12]

Houston Systems Manufacturing Co., custom-built a 600-barrel unitized mud system for use in Saudi Arabia. This system is trailer-mounted on retractable 10-foot tires, measures 73 by 23 feet, and rests flat on the ground on location. It has its own mud-mixing equipment, shale shaker, mud agitators, desanders, degassers, and disilters.[13]

DSC, Inc., of Richardson, Tex., has developed a drilling-soap concentrate that disperses rather than dissolve in the drilling fluid. It is claimed to be capable of reducing inhole torque by 50% after the initial circulation of the product. This soap concentrate, which is tradenamed Torkeuse, decreases the effects of hole drag, torque, and differential sticking; by improving pump efficiency and by increasing depth of the clear water drilling phase, costs are reduced. Most drilling-mud detergents are solutions of water-soluble soaps. The new additive is a concentrated suspension of complex soap which are only soluble in fresh water and practically insoluble in saturated salt water, making the additive disperse rather than dissolve.[14]

Hydril has developed a pump down type blowout preventer that provides complete closure inside the drill pipe when a blowout is imminent. The drop-in check valve is kept on the surface until needed and thus is not subject to downhole wear. The valve can be pumped or is allowed to float down the drill pipe to a special landing sub just above the drill collars. Once the valve is seated, it provides automatic check valve capabilities and downward circulation can be accomplished.

[11] World Oil. Drill Bit Research. V. 180, No. 5, April 1975, p. 15.

[12] World Oil. Drilling Research Lab. V. 180, No. 1, January 1975, p. 13.

[13] World Oil. Unitized Mud System. V. 181, No. 6. November 1975, p. 17.

[14] World Oil. Torque Reducing Additive. V. 180, No. 5, April 1975, p. 5.

During normal drilling operations, the only device downhole is a landing sub containing a stop ring. There is a slight restriction in the sub, but there is no interference with normal drilling operations, wireline operations, surveying, or other functions. The valve is removed by pulling the drill string and unscrewing the stop ring.[15]

Texaco Inc. has developed and is using a carbon/oxygen logging system that gives a direct indication of the oil zone and is independent of salinity and shaliness. The difficulty of using conventional radioactivity or electric logs to evaluate oil zones in low-salinity formations can now be solved with the carbon/oxygen logging system. The carbon/oxygen ratio increases in the oil zones compared with the water zones because of the combined increase in fluid carbon content and decrease in oxygen content. A similar increase in carbon/oxygen ratio is observed when changing from a sandstone to a limestone because of the difference in carbon and oxygen contents of the matrices. This matrix effect can be removed by using a calcium-to-silicon ratio that is measured simultaneously with a carbon/oxygen ratio.[16]

Warren Petroleum Co., a Division of Gulf Oil Co., has developed a gas liquids extraction plant which is highly portable. It is basically a rich gas process which can recover 65% to 75% propane and essentially all the heavier components from a small volume of rich gas (10 million standard cubic feet down to 100,000 standard cubic feet).

There has been little incentive to process small lean gas volumes because the amount of liquids involved is inadequate to support any substantial capital investment. This portable plant may fill the need for a rich gas process for small volumes. When gas volumes are larger, the process is modified to recover ethane and heavier components from lean gas. The plant is capable of unattended operations, and malfunction shutdown controls with telltale panel are incorporated in the design. Hydrates are controlled by methanol injection.[17]

Cities Service Co. is the world's first energy company to be approved by the Federal Communications Commission for offshore telecommunication service on Westar I, the first commercial domestic communications satellite. Under the program, using Western Union's satellite system, Cities Service will be able to use 12-voice-frequency channels providing voice, data, and facsimile capabilities for communication with their offshore work crews for a 2-year contract. Delivery is set for mid-September 1976.[18]

Pat Rutherford, Sr., a large semisubmersible drilling unit capable of drilling to 20,000 feet in 600 feet of water, will go to Texaco Trinidad, Inc.

Bethlehem Steel Corp., Beaumont, Tex., is building a jack-up rig with telescoping legs. This rig, J Storm VII, a new design, permits the mat-supported vessel to be operated in water depths of up to 375 feet. The rig is to be delivered to Southern Marine Drilling Co. under contract to Atlantic Richfield.

Further technical improvements are needed to accelerate petroleum production and increase proven reserves. Fieldwork and backup laboratory research are being performed by the U.S. Department of the Interior and private industries with grants to universities. It is hoped that new ideas and improvement in present technology will be beneficial in the quest for energy independence.

---

p Preliminary (except for crude oil and lease condensate production).

[1] U.S. Department of the Interior data for crude oil, unfinished oils, and plant condensate; U.S. Department of Commerce and Federal Energy Administration data for all other imports. Imports of crude oil include some Athabasca hydrocarbons.

[2] Represents the difference between supply and indicated demand for crude petroleum.

[3] U.S. Department of Commerce data.

[4] Produced at petroleum refineries. Demands for ethane and liquefied gases used for petrochemical feedstocks are excluded. Demand data for these products for petrochemical feedstocks used are included under the items "Ethane" and "Liquefied Gases."

[5] Includes isopentane.

Table 5.—Supply and disposition of crude petroleum (including lease condensate) in the United States

(Thousand barrels)

Supply and disposition	1971	1972	1973	1974	1975
Supply:

[1] Excludes service wells.

[2] Includes condensate wells.

[3] Gulf of Mexico, Northern is a new area, designated by the Bureau of Land Management for federally controlled Outer Continental Shelf (OCS) waters not previously mapped or leased. The area covers Gulf of Mexico OCS waters off the States of Texas, Louisiana, Mississippi, Alabama, and Florida.

---

[1] From reports of Committee on Petroleum Reserves, American Petroleum Institute. Included are estimated quantities of crude oil which geological and engineering data demonstrate with reasonable certainty to be recoverable from known reservoirs under existing economic and operating conditions.

[2] Includes offshore reserves.

[3] Includes Arizona, Missouri, Nevada, South Dakota, Tennessee, and Virginia.

[4] These data include the estimate of proved reserves in the Prudhoe Bay Permo-Triassic reservoir, discovered in 1968. The estimate is based on the analysis of extensive engineering and geologic data; however, revisions may be required when actual production performance becomes available.

---

[1] Includes 296,432,000 barrels in Delaware River Valley.
[2] Includes some Athabasca hydrocarbons.
[3] Includes 43 by truck.
[4] Includes Alaska, Arizona, Hawaii, Nevada and Oregon.
[5] Excludes crude oil imported for direct burning for fuel use by pipeline.

p Preliminary.

[1] Includes some Athabasca hydrocarbons.

[2] "Other hydrocarbons and hydrogen" is defined as including all hydrogen, process natural gas, tar sand bitumen, gilsonite, shale oil, and other naturally occurring hydrocarbon mixtures consumed as raw materials in the production of finished products.

[3] Production at gas-processing plants shown as direct transfers and omitted from the input and output at refineries.

Plant butane-propane mixture used at refineries	2,485	3,027	1,953	1,273
Domestic demand:				
Plant butane-propane mixture	928	503	437	2,105
Refinery butane-propane mixture:				
For fuel use	2,663	2,837	6,139	4,372
For chemical use	3,893	3,490	657	52
Total refinery butane-propane mixture	6,556	6.327	6,796	4,424
Total domestic demand	7,484	6,830	7,233	6,529
Isobutane:				
Production:				
At gas-processing plants	33,547	33,652	33,418	32,877
At refineries	2,079	2,576	3,181	2,219
Total production	35.626	36,228	36,599	35,096
Stocks, end of year:				
Plant isobutane:				
At plants	8,255	7,267	10,686	7,663
At refineries	1,431	959	1,758	1,771
Total plant isobutane stocks	9,686	8,226	12,444	9,434
Refinery isobutane	84	110	22	16
Total stocks	9,770	8,336	12,466	9,450
Plant isobutane used at refineries	34,262	35,112	29,200	35,887
Domestic demand: Refinery isobutane for chemical use	2,087	2,550	3,269	2,225
Kerosine (including range oil):				
Production:				
At refineries	79,027	79,422	56,646	55,495
At gas-processing plants	1,063	704	245	178
Total production	80,090	80,126	56,891	55,673
Stocks, end of year:				
At refineries	19,068	20,985	15,252	15,556
At plants	43	37	17	15
Total stocks	19,111	21,022	15,269	15,571
Imports	526	785	1,744	1,073
Exports	91	85	36	52
Domestic demand	85,852	78,915	64,352	57,990

See footnotes at end of table.

Table 22.—Salient statistics of the major refined petroleum products in the United States —Continued

(Thousand barrels)

Product	1972	1973	1974	1975 p
Distillate fuel oil:				
Production:				
At refineries	962,405	1,029,343	973,764	968,436
At gas-processing plants	1,220	835	261	214
Total production	963,625	1,030,178	974,025	968,650
Crude used directly as distillate	944	760	774	587
Stocks, end of year:

Stocks, end of year	94,761	99,154	106,031	106,352
Imports	45,705	50,161	44,228	12,985

p Preliminary.

[1] Includes underground stocks at plants and refineries, in thousands of barrels, as follows: At plants—ethane, 1974, 3,183; 1975, 5,549; propane, 1974, 57,186; 1975, 68,765; butane, 1974, 18,522; 1975, 17,778; butane-propane mixtures, 1974, 894; 1975, 1962; isobutane, 1974, 9,809; 1975, 6,891. At refineries (includes LRG)—propane, 1974, 3,730; 1975, 4,822; butane, 1974, 3,324; 1975, 2,417; butane-propane mixtures, 1974, none; 1975, 1; and isobutane, 1974, 507; 1975, 628.

[2] Includes No. 4 fuel oil, in thousands of barrels: 1972, 3,723; 1973, 3,449; 1974, 4,116; 1975, 5,035.

[3] Produced at petroleum refineries. Data for LRG petrochemical feedstocks are included with those for "Liquefied gases."

[4] Includes foreign crude oil to be burned as fuel, in thousands of barrels: 1972, 10,419; 1973, 19,105; 1974, 7,508; 1975, 13,559.

NOTE.—"Stocks at refineries" include stocks at refineries and bulk terminals operated by refining and products pipeline companies including pipeline fill, and stocks at independent bulk terminals. "Stocks at plants" include stocks at plants and terminals operated by natural gas processing companies and natural gas liquids stocks at terminals of pipeline companies, including pipeline fill.

p Preliminary. r Revised.

[1] American Petroleum Institute data for 1973. U.S. Department of Transportation, Federal Highway Administration data for years 1974 and 1975.

[2] Alaska, Hawaii and Nevada (1974-1975) included with California.

[3] Delaware and Georgia (1974) included with Pennsylvania.

[4] Nebraska and Missouri included with Kansas.

[5] Tennessee included with Kentucky.

[6] North Carolina and West Virginia included with Virginia.

[7] Wisconsin included with North Dakota.

[p] Preliminary. [r] Revised.

[1] Excludes direct imports by the military of naphtha-type jet fuel into PAD I, 6,318.000 barrels; PAD V, 1,664,000 barrels. Also excludes direct imports by the military of kerosine-type jet fuel into PAD I, 660,000 barrels; PAD V, 73,000 barrels.

[2] Excludes direct imports by the military of naphtha-type jet fuel into PAD I. 8,721,000 barrels; PAD V, 1,506,000 barrels. Also excludes direct imports by the military of kerosine-type jet fuel into PAD I, 100,000 barrels; PAD V, 44,000 barrels.

Definitions of terms used in this table:

Aviation gasoline—Any fuel in the gasoline boiling range for use in a piston-type aviation engine.

Jet fuel—Any fuel for use in an aviation turbine engine.

Airline—Sales to U.S. certificated air carriers, including air freight carriers, and international air carriers (if delivery is made in the United States), and to such other air carriers as supplemental or non-schedule carriers, air taxi, etc.

Factory—Direct sales to airframe and engine manufacturers. Does not include aviation fuels supplied to these accounts for the Defense Fuel Supply Center (DFSC).

General aviation—All nonmilitary sales which are not classified as airline or factory. Primarily made up of sales to distributors and airport dealers.

Military—Sales to Defense Fuel Supply Center and to other military agencies of the Government.

Nonaviation—Sales for use in turbine engines other than aviation turbine engines. Sales to electric utilities are included in this category.

[p] Preliminary.

[1] Represents crude oil used as fuel on leases and for general industrial purposes.

[2] Sulfur content in thousands of barrels: 0–0.50%, 1974, 97,671; 1975, 108,943; 0.51%–1.00%, 1974, 103,358; 1975, 111,516; 1.01%–2.00%, 1974, 105,028; 1975, 123,469; over 2.00%, 1974, 84,434; 1975, 107,029.

[3] Sulfur content in thousands of barrels: 0–0.50%, 1974, 15,304; 1975, 169,533; 0.51%–1.00%, 1974, 453; 1975, 65,700; 1.01%–2.00%, 1974, 1,018; 1975, 66,546; over 2.00%, 1974, 59; 1975, 112,324.

[4] Includes foreign crude oil to be burned as fuel, in thousands of barrels: District I, 4,787; district II, 2,721.

[5] Includes foreign crude oil to be burned as fuel, in thousands of barrels: District I, 6,588; district II, 6,312; district V, 659.

Table 55.—Posted price per barrel of petroleum at wells in the United States in 1975, by grade[1]

Grade	Price per barrel
Pennsylvania grade:	
Bradford and Allegheny districts	$6.83
Southwest Pennsylvania	6.12
Corning grade	5.17
Western Kentucky	5.20
Indiana–Illinois	5.20
Coldwater, Michigan	5.00
Oklahoma–Kansas:	
34°–34.9° API	5.11
36°–36.9° API	5.15
Texas, Panhandle (Carson, Gray, Hutchinson, and Wheeler Counties), 35°–35.9° API	5.10
West Texas, 30°–30.9° API (sweet)	5.11
Lea County, New Mexico, 30°–30.9° API (sour)	5.00
South Texas, Mirando, 24°–24.9° API	5.30
East Texas	5.20
Conroe, Texas	5.30
Texas:	
30°–30.9° API	5.05
20°–20.9° API	4.95
Louisiana, 30°–30.9° API	5.15
Caddo-Pine Island, Louisiana, 36°–36.9° API	5.04
Magnolia Smackover Limestone, Arkansas, 31°–31.9° API	4.84
Elk Basin, Wyoming (including Montana), 30°–30.9° API	4.86
California:	
Coalinga, 32°–32.9° API	5.01
Kettlemen Hills, 37°–37.9° API	5.26
Midway Sunset, 19°–19.9° API	4.28
Wilmington, 24°–24.9° API	4.63

---

[p] Preliminary.

[1] Imports for onshore of military jet fuel, distillate and residual fuel oils, and receipts from Puerto Rico, the Virgin Islands, and Guam included in these data are based on figures reported to the U.S. Department of the Interior. All other import figures are compiled from U.S. Department of Commerce data.

Phosphate Rock

By W. F. Stowasser [1]

In the United States, the average unit value of phosphate rock increased from $10.98 per ton, f.o.b. plant, in 1974 to $22.99 per ton, f.o.b. plant, in 1975. Although the published price of phosphate rock in international trade did not change during 1975, consumer resistance to higher price levels caused significant reduction in listed prices effective January 1, 1976, and negotiations between sellers and buyers established agreeable prices at less than published prices.

Additional marketing complications were created for both producers and consumers of phosphate rock as resistance to high prices for phosphate fertilizers backed up supplies in delivery pipelines in the United States and other major consuming and producing areas. As phosphate fertilizer prices declined in the United States, and with the domestic market not responding to the decline in prices, it was advantageous for U.S. integrated fertilizer producers to increase the level of shipments of relatively cheap fertilizers into world markets. It was equally advantageous for consuming countries to import fertilizer from the United States which was more than competitive with fertilizer produced in respective domestic plants utilizing exceptionally high-cost imported phosphate rock. This condition added pressure on major phosphate rock producers in North Africa and the United States to reduce the price of phosphate rock in international trade.

Estimated world production in 1975 was about 118.6 million short tons, about 3% below the 1974 record production level. After 4 years of demand exceeding production, demand declined and supplies were more than adequate in 1975. The sharpest decline in demand for phosphate occurred in West Europe where imports declined almost 7 million tons. The deterioration in export prices started in October 1975 when Morocco discounted published prices in an attempt to increase sales, which had markedly declined in 1975 from the record high in 1974.

In October, Morocco, which has a common boundary with the Spanish Sahara and had claimed the territory since 1956, mounted a march of an estimated 350,000 Moroccans into the Spanish territory with the declared objective of peacefully recovering the area. A Spanish minefield, about 10 miles south of the border, deterred further penetration into the territory and the march was terminated. Spain agreed to cede the territory to Morocco and Mauritania. In return, Spain will receive an as yet unspecified share in the Bu Craa phosphate operation, some continuing military rights at El Auin, and some fishing rights off the coast. The acquisition of the phosphate mine, plant, and reserves in the "Western Sahara" by Morroco will increase control over this commodity by the semi-monopoly of North African phosphate rock producers.

Legislation and Government Programs.—Applications by companies to mine phosphate rock in the Los Padres National Forest of California, the Caribou National Forest in Idaho, and the Osceola National Forest in northern Florida were not granted in 1975. Thomas S. Kleppe, Secretary of the Interior, deferred a decision on preference right leases in the Osceola National Forest in order to complete a 2-year study of the effects of phosphate mining on the underground water supply. A task force, under the direction of the Geological Survey, continued work on the Environmental Impact Statement on Development of Phosphate Resources in southeastern Idaho. The Environmental Impact Statement to assess the impacts of mining phosphate rock in the Los Padres National Forest was not released during 1975. The State of North Carolina did not issue a mining permit to the North Carolina Phosphate Corp. in 1975. Although several new mines were under construction in central Florida, mining permits were not granted in Manatee, Hardee, and De Soto Counties. Mine construction and permits in Polk and Hillsborough Counties were limited.

The Bureau of Mines was involved in a number of programs relating to Florida phosphates in 1975. A cooperative program was started in 1972 with the Florida phosphate industry to study the disposal and dewatering of phosphate waste slimes and continued through 1975. Several university grants were issued to supplement knowledge about phosphate waste fractions. A grant to the Florida Bureau of Geology was made to define and classify phosphate lands and correlate the data with the Environmental Protection Agency (EPA) and State of Florida radiation data. The Bureau of Mines initiated studies to determine the feasibility of recovering an acceptable grade of phosphate mineral from the Hawthorn Formation.

EPA studied radiation in structures on reclaimed land, studied worker exposure to radiation in mines and chemical plants, analyzed radiation levels in citrus fruit, analyzed radium 226 levels in central Florida well water, and analyzed radium 226 levels in recharge wells.

The phosphate mining industry, particularly in Florida, North Carolina, Idaho, and Tennessee, is subjected to regulation by county, State, and Federal governments. Compliance with all regulations has become expensive and time consuming for the industry and, in a majority of instances in 1975, delayed or deferred new phosphate rock mines. In Florida, permit requirements for major industrial developments that were in effect in 1975 can be summarized. On the Federal level, EPA, under authority of the Federal Water Pollution Control Act of 1972, and in compliance with the National Pollutant Discharge Elimination System (NPDES), requires that a permit be obtained for discharge of industrial waste water. If the source being permitted is a new source, that is, constructed after publication of proposed EPA guidelines, EPA must comply with the National Environmental Policy Act of 1969, which may require preparation of an Environmental Impact Statement. Under Section 404 of the

Federal Water Pollution Control Act, the U.S. Army Corps of Engineers may require approval for construction or mining activities in "wet lands." The Corps may be required to prepare an Environmental Impact Statement and, if also required by the EPA, it would be jointly prepared by both agencies. Prior to construction of a potential source of air pollution, the applicant must obtain approval under EPA's significant deterioration rule, 40 C.F.R., Part 52, which requires a preconstruction review of all proposed new major stationary sources to assure preservation of certain "clean air" areas.

The State of Florida Division of State Planning issued guidelines for determining the need for a "Development of Regional Impact" (DRI) report on any development which, because of its character, magnitude, or location, would have a substantial effect on the health, safety, or welfare of citizens of more than one county. For mining operations, a DRI would be required if the removal or disturbance of solid minerals or overburden over an area, not necessarily contiguous, would exceed 100 acres or whose water consumption would exceed 3 million gallons per day. After the DRI is submitted, the planning council reviews it and issues a report to the county. The planning council recommendation considers if the proposed action will have favorable or unfavorable effects on the natural resources of the region, the economy of the region, the public facilities such as water availability and sewer adequacy of the region, public transportation, and housing facilities. The recommendations are considered by the county governments concerned.

The State of Florida is involved in land reclamation. Guidelines of the Department of Natural Resources, chapter 16C–16 (1975), sets the rules for acceptance of credit for reclaimed land. Before a credit (a rebate of a portion of the severance tax) is granted, the guidelines must be met. The 1975 severance tax rate was 5% of the established value of the mineral at the point of severance with a credit of ad valorem taxes if a reclamation program is ongoing. The reclamation credit may be 50% of the remainder of the taxes if approved by the Department of Natural Resources. Criteria for credit under the 1975 law considers water quality, bank slopes, timing, revegetation, and safety. The Department of Natural Resources also regulates the construction specifications for water wells.

The State Department of Environmental Regulation was established in May 1975. This new Department combines the Department of Pollution Control, elements from the Department of Natural Resources, the Internal Improvement Trust Fund, the Bureau of Sanitary Engineering, and five water management districts. The Department authority covers National Pollution Discharge Elimination System permits; applicable to the phosphate industry were permits for industrial waste waters and air emissions, dam construction, dredge and fill activities, and sewer waste water.

The Florida Water Resource Act of 1972 established drainage districts throughout the State. The largest district is the Southwest Florida Water Management District (SWFMD) with jurisdiction over most of central Florida. SWFMD requires permits for well construction, water withdrawal or discharge, construction across or within, or other use of "works" of the water district, which includes the Peace River, its tributaries, and other river and water bodies. In December 1974, the district adopted rules for granting permits for the "consumptive uses of water." The policy adopted requires extensive hydrologic groundwater testing prior to consideration of permits for new withdrawals by phosphate companies. Issuance of a permit is contingent on volume and water-quality monitoring data, use (where possible) of recharge wells, utilization of surface water, maintenance of streams and rain gage stations, and the potential for "zero net withdrawal."

The Florida Counties of Alachua, De Soto, Hillsborough, Hardee, Manatee, and Polk have enacted mining or earth-mining ordinances to control mining activities. A zoning variance for these activities is granted based on a conceptual mining plan, followed by a permit-granting procedure that involves monitoring and an annual review of the mining methodology, reclamation progress, and compliance with regulations covering dam construction, settling ponds, easements to adjacent owners, soil vibrations, noise, flood plain restrictions, standards for water, air, ground water, rainfall, sewage effluent, and radiation; meeting reclamation standards as to slopes, lake depths, and time limitations; and continued monitoring of ground-water quality and quantity. The application for a zoning variance for a new development requires that a master mining and reclamation plan be prepared and that they include specifics on mining sequences, timing on mine development, specifications on reclamation, and water withdrawal plans. Concurrently, for new developments, an application for approval of a DRI must be filed with the county. The Regional Planning Council with jurisdiction submits a recommendation for denial or approval to the county. The county includes this recommendation in public hearing procedures for zoning variances and the DRI submitted material. If approved by the county, detailed mining plans are prepared by the company and submitted to obtain a mining permit. The county annually reviews and approves the mining permit. If the county does not approve the DRI, a minimum of 6 months must elapse before another application can be submitted.

DOMESTIC PRODUCTION

The total U.S. domestic production of marketable phosphate rock was 48,816,000 tons, an increase of 3,130,000 tons or 6.9% over that of 1974. The value of the marketable rock was $1,122,184,000, an increase of 124% over that of 1974. The average grade of phosphate ore mined in the United States was 12.5% P_2O_5 and the average grade of marketable rock was 30.8% P_2O_5, the same as that in 1974. The average weight recovery of concentrate and rock marketable as mined was 26.0%, down from the 29.3% average weight recovery in 1974. The average P_2O_5 recovery was 64.0%, considerably less than the 67.7% P_2O_5 average recovery in 1974. In the United States, Florida and North Carolina produced 40,669,000 tons (83.4%) of marketable phosphate rock, the Western States produced 5,825,000 tons (11.9%), and Tennessee produced 2,291,000 tons (4.7%).

Florida and North Carolina.—Production of marketable phosphate rock was 40,699,000 tons, an increase of 10.1% over that of 1974. The value of marketable rock was $1,000,352,000, an increase of $591,373,000, or 144.6% over that of 1974.

The average grade of phosphate ore mined was 11.8%, somewhat less than the average of 12.5% P_2O_5 in 1974, and the average grade of marketable rock was 31.3% P_2O_5, essentially the same as the average grade of 31.4% P_2O_5 in 1974.

The average weight recovery of concentrate and rock marketable as mined was 23.4%, down from an average weight recovery of 26% in 1974. The average P_2O_5 recovery was 62.2%, down from an average P_2O_5 recovery of 65.6% in 1974. The decline in weight and P_2O_5 recovery in 1975 can be partly attributed to the startup of new mines that only recovered pebble and stored concentrate feed for treatment in 1976. The increase in production in 1975 in Florida and North Carolina was characterized by moderate increases by a majority of the operating companies; the more significant gains were shown by Agrico Chemical Co., Borden, Inc., and Swift Chemical Co.

Agrico Chemical Co.; Borden, Inc.; Brewster Phosphates; Gardinier, Inc.; W. R. Grace & Co.; International Minerals & Chemical Corp. (IMC); Mobil Oil Corp.; Poseidon Mines, Inc.; Occidental Petroleum Corp.; USS Agri-Chemicals, Inc.; and Swift Chemical Co. produced marketable rock from Florida land-pebble phosphate fields. Howard Phosphate Co., Kellogg Co., Loncala Phosphate Co., and Manko Co. mined 28,000 tons of soft rock in Florida.

In North Carolina, Texasgulf, Inc., continued with plans to increase mining capacity at its Lee Creek mine. Added in late 1975 was an electric hydraulic dredge with a 30-inch cutter head to strip the top 40 feet of overburden and a new 45-cubic-yard dragline. With these additions and changes to the washing and concentration plants, Texasgulf, Inc. will have 5 million tons per year of marketable phosphate rock capacity. North Carolina Phosphate Corp., jointly owned by Agrico Chemical Co. and Kennecott Copper Corp., continued planning and working on a future phosphate rock mine and plant in North Carolina. Water-pumping permits were not issued to North Carolina Phosphate Corp. in 1975. Until the State of North Carolina issues the water permits, the schedule for construction of the proposed mine and plant could not be established in 1975.

In northern Florida, Occidental Chemical Co., a division of Occidental Petroleum Corp., completed the Swift Creek mine in late 1975. The plant is designed to produce 2.5 million tons per year and, together with the existing Suwanee River mine, Occidental will have a capacity in excess of 5 million tons per year.

In central Florida, Agrico Chemical Co. started operating the concentrator at its new Fort Green mine at yearend and plans to close the Palmetto mine in early 1976. The new Fort Lonesome mine of Brewster Phosphates was nearing completion in late 1975. The plant will start up in 1976 and produce at a rate of 2.8 million tons per year. W. R. Grace & Co.'s Hooker's Prairie mine, under construction about 4 miles southeast of Bradley, Fla., will be completed and will start producing at a rate of 2.5 million tons per year in mid-1976. T-A Minerals, Inc., has a washer and concentration plant under construction south of Mulberry, Fla. The plant is expected to start production in the second quarter of 1976.

A number of other companies have published their intentions to construct new plants or study the feasibility of opening new mines in Polk, Hillsborough, Manatee, Hardee, and De Soto Counties. Either the studies were incomplete or the necessary approvals and permits to proceed with mine construction were not obtained.

Western States.—Production of marketable phosphate rock was 5,825,000 tons, a decrease of 470,000 tons or 7.5% less than was produced in 1974. Lower production from mines in Idaho was the principal reason for lower production in the Western States.

The value of the marketable rock increased to $93,029,000, 25.7% higher than the value in 1974. The average grade of mined phosphate ore was 22.5% P_2O_5. The average grade of mined phosphate rock used without beneficiation was 26.6% P_2O_5. The average grade of beneficiated rock was 31.7% P_2O_5. The average grade of all marketable rock was 29.0% P_2O_5. Of the total phosphate rock produced in the Western States, 53.9% was used directly and the balance, 46.1%, was beneficiated. The weight recovery of the combined beneficiated concentrates and rock used as mined was 60%; P_2O_5 recovery was 77.3%.

Agricultural Products Corp., Monsanto Co., J. R. Simplot Co., and Stauffer Chemical Co. mined and processed phosphate rock in Idaho. In Montana, Cominco American, Inc., and Rocky Mountain Phosphate Co. recovered phosphate rock from underground mines near Garrison. Stauffer Chemical Co. mined phosphate rock in Wyoming and in two areas in Utah. The Meramec Mining Co., Sullivan, Mo., continued to recover apatite concentrates from its Pea Ridge iron ore mine tailings.

There were no new mines started in 1975. Work continued throughout the year on an Environmental Impact Statement by the U.S. Departments of the Interior and Agriculture. It was expected to be finalized and filed with the Council on Environmental Quality in mid-1976. The Statement was initiated in anticipation of development of new mines or expansion of existing phosphate mines in southeastern Idaho in the Caribou National Forest.

Tennessee.—Production of marketable phosphate rocks was 2,291,000 tons, a decrease of 120,000 tons or 5.0% less than reported in 1974. The value of the marketable rock increased from $18,465,000 in 1974 to $28,803,000 in 1975, an increase of 56.0%.

The average grade of mined ore was 19.9% P_2O_5, the average weight recovery of concentrates was 56.5%; recovery of P_2O_5 was 72.8%. A small quantity of rock was mined by several companies and used in electric furnaces without beneficiation.

Hooker Chemical & Plastic Corp., Monsanto Industrial Chemical Co., Stauffer Chemical Co., M. C. West, Inc., and the Tennessee Valley Authority mined phosphate rock in Tennessee and reduced the rock in electric furnaces to elemental phosphorus.

Table 2.—Production of phosphate rock in the United States, by State

[2] Data may not add to totals shown because of independent rounding.

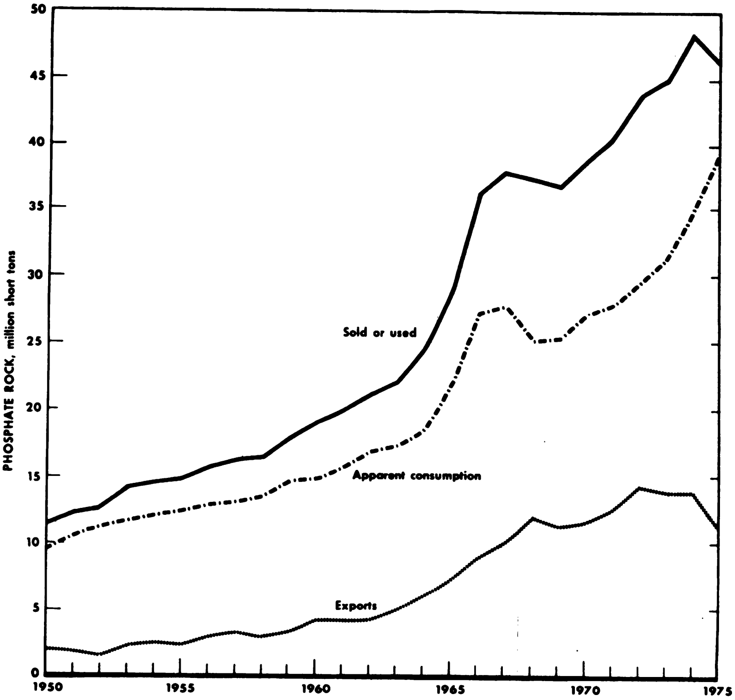

Figure 1.—Phosphate rock (sold or used), apparent consumption, and exports.

CONSUMPTION AND USES

Apparent consumption of marketable phosphate rock, as measured by sold or used, plus imports and less exports, declined 1.5% from that of 1974. According to producers' reports, the quantity of phosphate rock sold or used in 1975 was 46,439,000 tons, a decline from the peak 48,435,000 tons sold or used in 1974. Of the total sold or used in 1975, 73.6% was consumed domestically and 26.4% was exported.

The consumption pattern as reported by producers is shown in table 3. Of the total sold or used including both domestic and export markets, the distribution pattern was wet-process phosphoric acid 55.0%, normal superphosphate 2.2%, triple superphosphate 3.5%, defluorinated rock 0.4%, direct applications 0.3%, and elemental phosphorus and ferrosphosphorus 12.2% for a total of 73.6%.

The percent distribution by grade of marketable rock consumed in the United States and exported is compared with the percent distribution in 1973 and 1974 in the following tabulation:

Grade, BPL content [1]	Distribution (%)		
	1973	1974	1975
Less than 60%	8.7	5.6	9.4
60%–66%	11.9	20.8	14.7
66%–70%	40.9	42.0	48.4
70%–72%	12.3	12.2	10.8
72%–74%	16.7	11.6	10.7
Over 74%	9.5	7.8	6.0

[1] 1.0% BPL (bone phosphate of lime or tricalcium phosphate) = 0.458% P_2O_5.

Florida and North Carolina.—The quantity of phosphate rock sold or used decreased from 39,920,000 tons in 1974 to 37,921,272 tons in 1975. Of the total sold or used in 1975, 70.6% was consumed domestically and 29.4% was exported. Of that consumed domestically, 88.1% (23,600,000 tons) was used to produce wet-process phosphoric acid, 3.8% (1,008,000 tons) for normal superphosphate, 5.5% (1,487,000 tons) for triple superphosphate, 0.6% (168,000 tons) for defluorinated rock, 0.5% (133,824 tons) for direct applications, 1.4% (389,000 tons) for elemental phosphorus, and less than 0.1% for ferrophosphorus.

The percent distribution by grade of marketable rock sold or used from Florida and North Carolina in 1973, 1974, and 1975 is shown in the following tabulation:

Grade, BPL content [1]	Distribution (%)		
	1973	1974	1975
Less than 60%	0.3	0.2	0.1
60%–66%	9.7	17.0	14.8
66%–70%	45.9	47.2	55.0
70%–72%	14.1	14.3	11.2
72%–74%	18.5	11.9	11.5
Over 74%	11.5	9.4	7.4

[1] 1.0% BPL (bone phosphate of lime or tricalcium phosphate) = 0.458% P_2O_5.

Western States.—The quantity of marketable rock sold or used in 1975 increased 3.7% compared with 1974. Of the total sold or used in 1974, 81.4% was consumed in the United States and 18.6% was exported.

Of that consumed in the United States, expressed as a percent of the total sold or used from the Western States, 31.7% (1,944,000 tons) was used for wet-process phosphoric acid, 0.1% (8,000 tons) for normal superphosphate, 2.3% (140,000 tons) for triple superphosphate, 0.1% (4,000 tons) for defluorinated rock, less than 0.1% (1,501 tons) for direct applications, and 47.2% (2,890,000 tons) for elemental phosphorus and ferrophosphorus production.

The percent distribution by grade of marketable rock sold or used from the Western States in 1973, 1974, and 1975 is shown in the following tabulation:

Grade, BPL content [1]	Distribution (%)		
	1973	1974	1975
Less than 60%	37.7	35.8	38.8
60%–66%	22.8	22.5	18.2
66%–70%	20.4	23.5	25.9
70%–72%	6.0	3.5	12.2
72%–74%	12.6	14.8	9.9
Over 74%	.5	.4	--

[1] 1.0% BPL (bone phosphate of lime or tricalcium phosphate) = 0.458% P_2O_5.

Tennessee.—The quantity of marketable rock sold or used declined from 2,607,000 tons in 1974 to 2,393,000 tons in 1975. All of this rock was consumed in electric furnaces to produce elemental phosphorus and industrial chemicals. Most of the elemental phosphorus was converted to furnace-grade phosphoric acid, the base for sodium tripolyphosphate and dicalcium phosphate. A small quantity of elemental phosphorus was converted to anhydrous derivatives.

The percent distribution by grade of marketable rock sold or used from Tennessee in 1973, 1974, and 1975 is compared in the following tabulation:

Grade, BPL content[1]	Distribution (%)		
	1973	1974	1975
Less than 60%	66.4	19.7	80.9
60%–66%	19.8	75.6	17.5
66%–70%	12.9	4.7	1.6
70%–72%	--	--	--
72%–74%	.9	--	--
Over 74%	--	--	--

[1] 1.0% BPL (bone phosphate of lime or tricalcium phosphate) =0.458% P_2O_5.

1975	2,393	617	29,921	12.50

STOCKS

Stocks of marketable phosphate rock in the United States increased from 6,974,524 tons at the beginning of the year to 9,946,045 tons at yearend. The increase returned stocks to 1973 levels, replacing heavy stock drawdowns in 1974.

In Florida and North Carolina, stocks increased from an abnormal low of 5,578,446 tons at the beginning of the year to 8,533,323 tons at yearend. In Tennessee, stocks increased from 275,803 tons to 307,364 tons during the year. In the Western States, stocks were rather stable, decreasing from 1,120,275 tons to 1,105,358 tons during the year.

PRICES

Prices for the various grades of phosphate rock sold in the domestic market are not published by either producers or consumers. Contracts are negotiated between buyer and seller, and terms are not standard. Some companies that sell merchant rock domestically publish prices that, when compared, show differences particularly between phosphate rock sold from different producing areas in the country. The Chemical Marketing Reporter publishes prices for various grades of Florida land-pebble phosphate rock and an example of the price schedule is shown in table 8. These prices may be an indication of the December 1976 new contract price levels in the domestic market.

The price of Western or Tennessee phosphate rock consumed in electric furnaces is not published. Acid-grade rock from the Western States is, for the most part, either captively consumed or exported. Only a small tonnage is sold in the merchant market.

Table 8.—Prices of Florida land-pebble phosphate rock, washed, dried, and unground, in bulk carload lots, f.o.b. mine
(Per short ton)

Grade, BPL content	Price
77%–76%	$52.00
75%–74%	47.00
72%–70%	40.00
70%–68%	35.50
68%–66%	31.00

Source: Chemical Marketing Reporter, v. 208, No. 22, Dec. 1, 1975, p. 48.

The average 1975 unit value[2] of marketable rock as reported by producers, and estimated when unspecified, was $22.99 per ton f.o.b. plant, an increase of 109% over the $10.98 per ton reported in 1974. The average unit value of land-pebble rock reported sold or used in the domestic market from Florida and North Carolina increased from $10.95 per ton in 1974 to $24.46 per ton in 1975. In the Western States, the unit value of marketable rock sold or used increased from $12.08 per ton in 1974 to $15.64 per ton in 1975. The unit value of marketable rock sold or used in Tennessee increased from $7.90 per ton in 1974 to $12.50 per ton in 1975.

The average unit value of phosphate rock exported from the United States increased from $13.96 per ton in 1974 to $34.98 per ton in 1975, a 151% increase. The unit value of marketable rock exported from Florida and North Carolina increased from $13.84 per ton in 1974 to $36.57 per ton in 1975. The unit value of phosphate rock exported from the Western States increased from $16.40 per ton in 1974 to $19.32 per ton in 1975. Tennessee rock was not exported.

The Phosphate Rock Export Association, Tampa, Fla., decreased its prices of phosphate rock on January 1, 1976, from prices that had remained unchanged since October 1, 1974. The prices are shown in table 9.

The Office Cherifien des Phosphates of Morocco increased phosphate rock prices on January 1, 1975, and in October of 1975 started discounting in the range of from $6 to $12 per metric ton in an attempt to stimulate sales. Further price reductions were made effective January 1, 1976, but it was understood that the listed prices were discounted to lower levels for reasons of exclusivity of supply, size of orders, and customer relations. The prices published in Fertilizer International[3] are shown in table 10.

---

[2] Value, if sold, net selling price f.o.b. plant, or, if used, estimated value from comparable selling prices or developed price; that is, cost plus overhead and profit.

72%	60.75	43.00

FOREIGN TRADE

Exports of phosphate rock as reported by producers declined 11.7% to 12,272,000 tons in 1975. Of the total exported in 1975, 90.7% originated in Florida and North Carolina and 9.3% originated in the Western United States. Exports from Florida, the principal source of rock for the export market, declined from the level of shipments made in 1974. Exports from the Western States in 1975 increased 76% over that exported in 1974.

The average calculated unit value of exported phosphate rock in 1975 was $34.98 per ton, considerably greater than the average value of $13.96 per ton reported in 1974.

Imports in 1974 were 36,000 tons, considerably less than the 182,000 tons reported in 1974. The unit value of the imported phosphate rock declined from a high of $49.45 per ton in 1974 to $43.35 per ton in 1975. A small tonnage of rock was imported from Mexico; however, most of the 37,000 tons imported originated in the Netherlands Antilles.

WORLD REVIEW

Although plans and projects in some principal producing areas of the world, conceived in prior years, were executed in 1975, others were deferred since demand for phosphate rock was depressed by the continuing high price structures established in 1974 and the disparity between the relatively high world prices of phosphate rock and declining world prices of phosphate fertilizers.

Australia.—Shipments of phosphate rock from the Duchess deposit, located about 27 miles south of Duchess, Queensland, were initiated in March. Duchess is situated about 38 miles southeast of Mount Isa. The mine product was trucked to the railhead at Duchess and loaded into cars for the haul to Townsville on the east coast. The railroad will be extended to the Duchess deposit and when completed in 1976, phosphate rock will be moved by rail from both the Duchess and associated Ardmore deposits at a rate of 1.1 million short tons per year. In 1977, shipments at a rate of 3.3 million short tons per year are planned. The reserves of the Duchess-Ardmore deposits are estimated to be 44 million short tons of direct-shipping ore grading 31% P_2O_5 and 1,500 million short tons grading 17.5% P_2O_5. Development of these deposits will probably delay development of the Lady Annie and Lady Jane phosphate deposits northwest of Mount Isa and closer to the Gulf of Carpentaria.

Canada.—International Minerals & Chemical Corp. reported the discovery of a carbonatite-alkalic rock complex containing apatite in Cargill Township in northern Ontario. The general location is about 28 miles southwest of Kapuskasing and about 400 miles northwest of Toronto. The discovery was described as significant, but additional drilling and analysis must be completed before the deposit can be fully characterized.

Egypt.—Studies of the phosphate rock deposits in the Abu Tartar plateau were reported by the General Organization for Industrialization of the Ministry of Industry and Mineral Wealth. The deposits are west of El Kharga approximately 291 miles south-southwest of Cairo. The Ministry reports nearly 660 million short tons of proven reserves. Various plans have been announced, but not finalized, to develop the deposit, construct a rail line from Abu Tartar spanning the Nile to the Red Sea, and a port on the Red Sea to export phosphate rock or triple superphosphate.

Finland.—The Finnish Government decided to develop phosphate deposits in Savukoski-Sokli to recover 55 million short tons of apatite concentrates. By 1980, production could reach 772,000 short tons per year.

Kemira Oy mined a trial quantity (110,000 short tons) from an apatite deposit in central Finland. An 11-ton-per-day pilot-plant test will determine the feasibility of producing from this deposit on a commercial scale.[4]

Israel.—Negev Phosphates Ltd., a part of Israel Chemicals Ltd., will develop a new mine at Nahal Zin to produce 2 million tons per year of washed phosphate rock. The port of Ashdod will be expanded, a rail line installed to Nahal Zin, brackish water wells drilled, and construction of a washing plant to leach chlorine out of the rock will require a total investment of $85 million. By 1978, Israel will have a total capacity of 3 million tons per year of phosphate rock.[5]

Jordan.—The expansion program at El Hassa and Ruseifa is designed to increase production to 5 million short tons in 1976, 7 million tons in 1977, 8.5 million tons in 1978, and 9.5 million tons in 1979. It is assumed that production will remain at or about this level until 1995. The railroad line from Batn-el-Gul to Aqaba, a distance of 63 miles, can only carry 1.8 million tons per year. Studies are underway to increase the carrying capacity of the railroad from El Hassa to Aqaba, a distance of 142 miles to permit shipments of 5 million tons by 1977 and as much as 8 to 9.5 million tons by 1979.

Mexico.—Since press reports in 1974 of the discovery of 3 billion short tons of phosphate rock in the Baha California peninsula of Mexico, press reports in 1975 indicated reserve estimates to be 500 million tons or 300 million tons; other reports suggested that estimates of the Baha reserves are far from exact at this time.[6]

Wall Street Journal. Mexico to Invest $184 Million in Phosphate Rock Mining. June 16, 1975.

Morocco.—The decline of phosphate rock exports in 1975, compared with those in 1974, was attributed to the higher prices established at the beginning of 1975. The market position in phosphate rock deteriorated steadily throughout the year. In November 1975, Morocco reduced the price of phosphate rock by about $8 per metric ton in an attempt to increase sales. In the short term, because of the depressed market, Moroccan plans to export phosphate rock, phosphoric acid, and solid intermediates were curtailed. If the effort by Morocco's King Hassan II to annex the Spanish Sahara is successful, Morocco will control the world's largest reserves of phosphate rock and improve the long-range prospects of Morocco's position in world trade of this commodity.

Peru.—Plans for the Bayovar fertilizer complex to produce and export phosphatic fertilizers in 1976 were announced. Minero Perú, the State-owned mining company, is expected to furnish raw materials for the production of 838,000 short tons per year of fertilizers. Production will be from 606 short million tons of proven reserves.[7]

Senegal.—President Leopold S. Senghor, in his annual address on March 24, 1975, discussed the development of the new Tobene phosphate rock mine. It is located about 4 miles from the Taïba mine and could open as early as 1978. At least three international corporations are bidding on the construction contract for the mine and plant. Exploration programs to locate phosphate rock in northern, eastern, and southern Senegal were conducted cooperatively in 1975 by the Government of Senegal, United States Steel Corp. Phosphates de Thies, and the Bureau de Recherches Géologiques et Minières.

Spanish Sahara.—The Spanish Government began moving troops out of the Spanish Sahara at yearend. After the Moroccan army moved into the capital city and surrounding areas, a civil administration was organized.[8] With the Spanish presence in the Spanish Sahara ended, Morocco will operate the Bu Craa mine and plant. Arrangements with Spain were not announced; however, speculation suggests that Spain will continue to receive phosphate rock from Bu Craa. Reserves previously estimated by Fosfatos de Bu Craa S.A. to be 1.9 billion short tons were increased to 10 billion tons by new discoveries.[9]

Syrian Arab Republic.—Syria concluded an agreement with Romania to conduct a survey and estimate reserves of phosphate rock in the Syrian desert. Romania will also construct a plant to process phosphate rock in 1977. The Syrian Government forecast that production will increase to more than 3 million tons per year by 1980. It will be necessary to construct a railway system to transport phosphate rock from the mines to ports on the Mediterranean Sea.[10]

Tunisia.—Compagnie des Phosphates et du Chemin de Fer de Gafsa's new mine at Sehib, southwest of Gafsa in central Tunisia, was scheduled to start production in 1976. Reserves have been estimated to exceed 66 million short tons. Each of three planned longwall faces will have a capacity of 2,200 short tons per day. Initial production will be 1.3 million short tons per year. In addition to developing the Sehib mine, Sfax-Gafsa Co. is also developing the M'rata and Kev es Schfair mines in the Gafsa Phosphate Basin. Completion of these programs will increase Tunisian phosphate rock capacity from 4.4 to 5.7 million short tons in 1978.[11]

U.S.S.R.—The first commercial exploitation of the Kovdor apatite deposit on the Kola peninsula began with the startup of a 970,000-ton-per-year concentration plant.[12]

A large deposit, estimated to contain 3 billion tons of phosphate rock, was reportedly discovered in Yakutia in eastern Siberia. If fertilizers are produced from this deposit, the need to ship similar materials from the Urals and European U.S.S.R. would diminish.[13]

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Belgium, Indonesia and Tanzania may have continued to produce phosphate rock, and South West Africa produced guano, but output is not officially reported and available information is inadequate for formulation of reliable estimates of output levels.

[2] Estimate by International Superphosphate Manufacturer's Association, on the basis of a marketable product averaging 34.8% P_2O_5; differs with data reported in the U.S.S.R. chapter of Volume III of the Minerals Yearbook which are reported in terms of two products of differing grade.

[3] Exports.

[4] Less than ½ unit.

TECHNOLOGY

The Albany Metallurgy Research Center of the Federal Bureau of Mines, Albany, Oreg., initiated a program to develop new procedures for recovering phosphorus from the complex phosphate rock deposits located in the Western United States. A number of phosphate beds were identified and sampled for beneficiation studies. One sample from the Dry Valley area of Idaho was characterized as a low-grade phosphatic shale, averaging 11 feet in thickness and assaying 10% to 11% P_2O_5. Another sample from the Conda, Idaho, area was somewhat higher in P_2O_5 content and had an unusually high carbon content, ranging from 11% to 16%. A third sample from the Sublette Range area on the Idaho-Wyoming border was obtained and beneficiated. Characterization and beneficiation studies of these materials include attrition-scrubbing-sizing, washing and sizing, calcining, and grinding and flotation circuits. A 60-pound-per-hour continuous-circuit beneficiation plant was constructed and some shakedown tests were made. Startup problems will be corrected, and the plant will be used to evaluate a combination carbonate-silica flotation circuit on mixed altered-unaltered phosphate rock.

The Albany Metallurgy Research Center also designed and assembled a continuous unit to demonstrate production of phosphoric acid by direct sulfuric acid digestion of Florida land-pebble matrix samples. The goals were to produce phosphoric acid with improved P_2O_5 recovery without creating the difficult-to-dewater slime normally generated in washing and classifying Florida phosphate-bearing matrix. In initial tests, conditions were established in the sulfuric acid digestion reactor to promote large crystals of gypsum and increase filtration rates. This was accomplished by increasing the digestion temperature from 60° C to 90° C and controlling the sulfate level in the slurry. The phosphoric acid derived from matrix digestion approximated the composition of commercial acid produced from phosphate rock concentrates except for the aluminum content, which was about double that of commercial acid. Purification of the acid produced by matrix digestion to a quality equivalent to commercial acid has not been achieved. Preliminary studies utilizing ion-exchange systems and precipitation procedures were inconclusive.

Studies at the Bureau of Mines Tuscaloosa Metallurgy Research Laboratory, Tuscaloosa, Ala., to investigate the effects of reagents on settling rates, gelation, and dewatering behavior of Florida phosphate slimes continued in 1975. The effects of organic, inorganic, and commercial reagents on high-grade attapulgite slime from the Florida field were measured at different reagent concentrations. Measurements of viscosity and conductivity were made, and the reagent-slime mixtures were adjusted to different pH levels with sodium hydroxide and hydrochloric acid prior to centrifuging to simulate a 30-day settling test. The dewatering effect was generally unsatisfactory, conforming to the results of prior tests with various reagents and pH modifications. In another series of tests, reagents were mixed with waste tailings sand, then added to a plant slime and allowed to settle. A number of reagents were tested with this procedure, but the best results were obtained when flocculant AP–30 was used.

A thick stringy mixture was formed when attapulgite slime was mixed with a polyethylene oxide polymer. When this mixture was combined with a second reagent, the system released more than 90% of its water as a clear liquid. A coherent plastic mass containing the slime solids remained. Laboratory tests indicated that this result could be achieved with a polymer addition of 7.7 pounds per ton.

The correlation of slime composition and filtration behavior was studied. A procedure developed by modifying an American Petroleum Institute standard method for evaluating drilling muds was used as a rapid test for studying relative filtration rates of clay mineral combinations that occur in Florida phosphate slimes. It was found that montmorillonite suspensions filter very slowly and attapulgite and kaolinite suspensions filter rapidly. The variation in filtration rates was probably a result of the closely stacked structure of plates and sheets of montmorillonite, the needlelike structure of attapulgite, and the hexagonal flaky structure of kaolinite. Because of the similarity in filtration behavior of attapulgite and kaolinite suspensions, a number of electrolytes were evaluated for their effect on the filtration of kaolinite suspensions. Calcium salts, especially CaO, were most effective on the filtration rate of kaolinite suspensions.

Static filtration, wicking, and compaction methods of dewatering Florida phosphate slimes were investigated. Laboratory studies utilizing a column of moving screens was effective when the experiment was performed in two stages. With slimes containing from 4% to 7% solids, solid concentrations of from three to five times the original were achieved. A serious disadvantage to this procedure is the difficulty of applying the technique on a commercial-plant scale. Static filtration was found to be effective. Newspapers were wrapped around wire screen cylinders and immersed vertically in the slime. This type of system could be used to dewater existing slime ponds. After 2 weeks, the percent solids increased to 25. Dewatering slimes to 35% solids was accomplished by electro-dewatering procedures. In wicking or static filtration tests, individual wicks did not appear to dewater a very large area. This type of system, with wicks molded with resin-sand mixtures, may have potential for larger scale field tests.

Samples of the Florida Hawthorn Formation were obtained for characterization studies, and some beneficiation tests of selected samples were conducted. After removing primary slimes, the ore was ground to pass 150 mesh and again deslimed. The pulp was conditioned with phosphoric acid to depress the phosphate and a fatty acid to float the dolomite. Recovery was very low, and the tailings, after cationic flotation of the insoluble material, analyzed 27.3% P_2O_5, 45.1% CaO, and 1.6% MgO. Additional tests showed that improved results were obtained when the ore was ground to pass 65 mesh, deslimed at 200 mesh with a loss of 60% of the original sample weight and thickened to 65% solids. After conditioning with a fatty acid-mineral oil combination, a rougher phosphate concentrate was floated that analyzed 31.8% P_2O_5. Preliminary tests indicated that after dolomite removal, the phosphate will respond to single-stage flotation without depressants. In future tests, only Hawthorn Formation samples that have 5% or more P_2O_5 will be tested.

At the annual meeting of the Fertilizer Industry Round Table in Washington, D.C., in December, Davy Powergas Inc., of Lakeland, Fla., was presented with the John C. Vaaler award for its wet-grinding process for phosphate rock. The process eliminates the need to dry the rock and saves 2.5 gallons of fuel oil per ton of rock. In addition, a smaller mill can be used, dust pollution is eliminated, and dust-collecting systems are not required, further reducing power costs and investment dollars.

Two large slurry-handling systems are now in use for storing and reclaiming phosphate ore at the Phosphoria and Noralyn, Fla., operations of International Minerals & Chemical Corp. Developed by Marconaflo Inc., a subsidiary of Marcona Corp., San Francisco, Calif., the slurry-handling systems are capable of handling more than 10 million tons per year of washed phosphate flotation plant feed and provide a continuous slurry flow at a controlled solids content (around 40%), independent of fluctuations in the output of the mining and washing operations, which can adversely affect production, especially at times of peak demand.

At each site there are two large ponds, each about 300 feet across and 25 feet deep, separated by a central dam. While phosphate slurry is being withdrawn from one pond, the other is being filled with slurry from the washing plant and free water allowed to drain off. Recovery is effected by a high-powered water jet that can be projected horizontally for distances up to 100 feet from a special assembly on the floor of each pond. This undercuts the material, and the slurry flows to a sump around the jet assembly from which it is pumped to the flotation plant. Total storage capacity at each site is about 60,000 short tons. The system acts as a surge between the mine and washing plant and the flotation system.

The Marconaflo concept may find wider use in the phosphate industry. There is interest in long-distance slurry transport of mined phosphate rock where rail construction costs would be prohibitive. It has been proposed that the production be moved via pipeline from Queensland Phosphate's Lady Annie/Lady Jane project to Sweers Island.[14]

Platinum-Group Metals

By W. C. Butterman[1]

In the United States, mine production rose by nearly 49% above that of 1974, to 18,920 ounces, while refinery production, including both toll and nontoll metal and derived almost entirely from secondary materials, fell 9%, to 1.3 million ounces. Sales of metal to industry dropped by 671,000 ounces, to 1.3 million ounces, or 34% below the 1974 level. Industry stocks dropped 24% to 849,000 ounces. Exports decreased 21% to 660,000 ounces, and imports decreased 44% to 1.8 million ounces.

World mine production of the platinum-group metals in 1975 remained at 5.8 million troy ounces, the level of 1974, as increases in nickel-byproduct production in Canada and the U.S.S.R. offset a production decrease in the Republic of South Africa. These three countries accounted for more than 99% of world mine production. The small remainder came from seven countries, including the United States. Demand for the platinum-group metals decreased in 1975 owing to economic recession in the industrialized countries. Demand for platinum in Japan countered the trend, however, so that Japanese consumption of platinum-group metals grew 14% in 1975. It was estimated that about one-third of the world's platinum-group metals was consumed by Japan, almost another third by the United States, and the remainder shared about equally between other market economy countries, and the centrally controlled economy countries.

r Revised.

[1] The platinum group comprises six metals: Platinum, palladium, iridium, osmium, rhodium, and ruthenium.

[2] Recovered from platinum placers and as byproducts of copper refining.

Legislation and Government Programs.—U.S. Government inventories of platinum, palladium, and iridium remained unchanged in 1975. The three metals were in excess of stockpile objectives established in 1973. The Environmental Protection Agency held hearings on automotive emission standards and technology early in the year, and shortly thereafter announced a further 1-year delay, through model year 1977, in the application of the original 1975 standards.

Total	452,645	1,254,994	17,002
Objective	1,314,000	2,450,000	97,761

[1] Includes 13,048 troy ounces non-stockpile-grade material.
[2] Includes 2,204 troy ounces non-stockpile-grade material.
[3] Includes 12 troy ounces non-stockpile-grade material.

DOMESTIC PRODUCTION

Domestic mine production of the platinum-group metals in 1975 was 18,920 ounces. Most of the metal was recovered as a byproduct of copper refining; the remainder came from a placer deposit at Goodnews Bay, Alaska, the only domestic deposit mined primarily for the platinum-group metals.

U.S. refinery production, including toll-refined metal, was 1.3 million ounces. Of this, 97% was secondary metal. The quantity of secondary metal refined on a nontoll basis was 270,000 ounces, while tolled secondary metal, always a much larger quantity, amounted to about 1.0 million ounces. The small quantity of primary metal was derived from crude platinum from Alaska and from anode slimes produced in the electrolytic refining of copper from the Western States. Compared with 1974 levels, mine production in 1975 rose 49% while total refinery production fell 9%. The quantity of secondary material refined on a nontoll basis declined 17%, and tolled secondary material fell 6%.

The Johns-Manville Corp. continued exploration and development of claims in the Beartooth Mountains of southern Montana. Grade in the mineralized horizon averaged 0.43 to 0.46 ounce of platinum plus palladium per ton, with 0.15% copper plus nickel. The ratio of platinum to palladium in samples was about 1 to 3.5. Feasibility studies were expected to be completed by mid-1976.[2]

CONSUMPTION AND USES

Sales of the platinum-group metals to U.S. industry totaled 1.3 million ounces in 1975. The automotive industry was the largest purchaser, accounting for 28% of total purchases, followed by the chemical industry (24%), the electrical industry (17%), the dental-medical industry (10%), the petroleum refining industry (9%), and other industries (12%). Compared with 1974 levels, sales of the whole group in 1975 were down 671,000 ounces, or 34%. As shown in table 4, platinum sales at 699,000 ounces comprised 53% of total sales, followed by palladium (542,000 ounces), 41%; rhodium, 3%; ruthenium, 2%; and iridium, 1%.

In general, the uses of the platinum-group metals remained the same as in previous years, those uses being related to the outstanding catalytic activity, refractoriness, and resistance to chemical corrosion possessed by the six metals of the group. However, the pattern of usage of palladium, which had changed in 1974 with the advent of automotive emissions control catalysts and the replacement by the telephone industry of pure palladium relay contacts with palladium-silver contacts, changed further as the full impact of the telephone industry's reduced consumption was felt. Although automotive industry purchases of palladium and platinum declined in 1975, the quantity of metal actually consumed, as distinguished from being put into inventory, was larger in 1975 than in 1974.

[1] Comprises primary and nontoll-refined secondary metals.

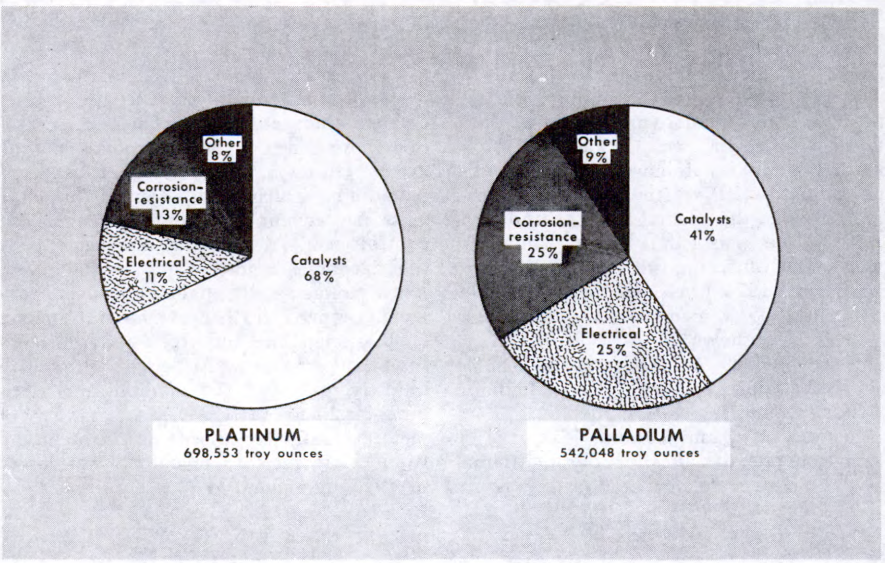

Figure 1.—Uses of platinum and palladium in 1975.

STOCKS

Stocks of platinum-group metals held by refiners, importers, and dealers decreased 24% in 1975. Iridium stocks remained essentially unchanged from 1974 levels, but stocks of the other metals declined as follows: Platinum 21%; palladium 30%; osmium 28%; rhodium 3%; and ruthenium 44%. (It should be noted that these are partial industry stocks, since the Bureau of Mines does not collect inventory data from end users of the platinum-group metals, some of whom may hold sizable inventories). In addition, there were Government stockpiles of platinum, palladium, and iridium.

Table 5.—Refiner, importer, and dealer stocks of platinum-group metals in the United States, December 31 [1]

r Revised.

[1] Includes metal in depositories of the New York Mercantile Exchange; on December 31, 1975, this comprised 137,000 ounces of platinum and 10,300 ounces of palladium.

PRICES

The producers' price for platinum started the year at $190 per troy ounce and was lowered to $170 in February and again to $155 in April; raised to $170 in August, and was reduced again to $155 in October. Producers' palladium began the year at $150 per troy ounce, but was reduced to $120 in February, to $80 in June, and to $50 in October. Producers' rhodium and iridium prices held at $350 and $500 per troy ounce, respectively, during the first 9 months of the year, and then were reduced to $300 and $400, respectively, in October. Osmium and ruthenium prices remained unchanged at $200 and $60 per troy ounce, respectively.

Dealers' prices for rhodium and iridium began the year above producers' prices, but lost ground quickly in January and were well below producers' prices thereafter. Dealers' prices of the other four metals were below producers' prices all year. Average prices for the year, calculated at the low ends of the ranges of weekly averages published by Metals Week, follow:

	Producer (per troy ounce)	Dealer (per troy ounce)
Platinum	$164.23	$150.40
Palladium	93.46	66.48
Iridium	476.92	394.85
Osmium	200.00	136.09
Rhodium	338.46	278.34
Ruthenium	60.00	45.15

FOREIGN TRADE

Exports of unwrought and semimanufactured platinum-group metals decreased 21% in 1975 compared with 1974, to 660,000 ounces, of which nearly half was platinum. The exports were valued at $88 million. Of the exports, 26% went to Japan, 21% to West Germany, 15% to the United Kingdom, and the remainder to 45 other countries.

Imports fell 44% in 1975, to 1.8 million ounces, and value dropped 46%, to $273 million. Of total imports, 56% was platinum and 36% was palladium. Compared with 1974 levels, and including estimates of metal in composite import classes, platinum imports decreased 32%, while palladium imports fell 57%. Nearly half of total imports came directly from the Republic of South Africa, and a substantial part of the 20% of imports that came from the United Kingdom originated in South Africa. Only 18% of total imports came from the U.S.S.R., a reflection of the sharp drop in palladium imports. Imports of each metal were estimated as follows:

	Thousand troy ounces
Platinum	1,025
Palladium	655
Iridium	23
Osmium	3
Rhodium	94
Ruthenium	20
Total	1,820

WORLD REVIEW

World mine production of the platinum-group metals in 1975 was 5.8 million ounces, the same level as in 1974. The Republic of South Africa and the U.S.S.R. accounted for 45% and 46%, respectively, of mined output, while nearly all of the remaining 9% came from Canada, except for a few thousand ounces from seven other countries, including the United States.

U.S. mine production was 18,920 ounces, compared with 12,657 ounces in 1974. Most of the output was byproduct metal from electrolytic copper refining; the remainder came from the placer deposit at Goodnews Bay, Alaska, where the platinum-group metals are mined as principal products.

Placer mining in Colombia yielded about 22,000 ounces. This level is substantially below the level attained in the early 1970's. All dredging was done by Mineros Colombianos, the Colombian company which in 1974 purchased two U.S.-owned mining companies—Cia. Minera Chocó Pacífico, S.A., and Pato Consolidated Gold Dredging, Ltd. Small quantities of platinum-group metals were obtained as byproducts of copper and nickel refining in Japan, Finland, the Philippines, and Australia.

Canada.—Production of platinum-group metals in Canada increased 12% to 430,000 ounces. The platinum-group metals were byproducts of nickel-copper mining in the Sudbury, Ontario, and Thompson, Manitoba, districts. The principal producers were International Nickel Co., Inc., and Falconbridge Nickel Mines, Ltd. Exploratory drilling continued at the platinum-group metals discovery at Lac des Iles, 50 miles northwest of Thunder Bay, Ontario. Texasgulf, Inc., which took an option on the property early in 1975, reported that possible reserves of about 22.5 million ounces were indicated by drilling. Grade in the mineralized zone ranged from 0.1 ounce for platinum-group metals per ton to more than 0.2 ounce per ton, with palladium being more abundant than platinum.[3]

South Africa, Republic of.—South African mine output of platinum-group metals in 1975 was 2.6 million ounces, a 7% reduction below the 1974 level. South Africa, in 1975, was the world's largest producer of platinum (63%), rhodium (59%), and ruthenium (48%), and may have been the largest producer of osmium as well. A very small quantity of osmiridium was recovered as a byproduct of gold mining, but essentially all of the platinum-group minerals were mined as the principal products from mines in the Merensky Reef, an extensive rock formation in Transvaal Province. The Reef alone contains more than half of the world's know resources of platinum-group metals, in an ore that grades about 0.2 ounce of platinum-group metals per ton, plus 0.15% copper-nickel. Estimated capacities and production of the four companies that mined platinum-group metals are as follows:

---

[3] Texasgulf, Inc. Third Quarter Report, 1975. Pp. 5–6.

Company	Estimated 1975 yearend capacity, platinum-group metals (thousand ounces)	Estimated 1975 production platinum-group metals (thousand ounces)
Rustenburg Platinum Mines Ltd	2,250	1,490
Impala Platinum Ltd	1,530	970
Western Platinum Ltd	150	130
Atok Platinum Mines, Pty., Ltd	40	30

In February, Rustenburg, in order to balance supply with the weakened demand for platinum in the western countries, began to cut its production by 25%, to a rate of about 1,450,000 ounces of platinum-group metals per year. It also slowed and changed its expansion plans.[4] At about the same time, Impala decided to hold its production at about 970,000 ounces per year and to substantially reduce its expenditures for expansion.[5]

Lonhro, Ltd., announced plans to build an extension to its refinery at Brakpan, featuring an ion exchange refining method developed by the National Institute for Metallurgy.[6]

U.S.S.R.—Production of platinum-group metals in the U.S.S.R. in 1975 was estimated at 2.6 million ounces, a 6% increase over the 1974 level. The U.S.S.R. was the world's largest producer of palladium (64%) and iridium (54%) in 1975. Most of the platinum-group metals were recovered as byproducts of nickel-copper mining in the Norilsk-Talnakh region of Northwestern Siberia, and from the Petsamo-Monchegorsk region of the Kola Peninsula. A small quantity was recovered, along with gold, from the old platinum placer deposits in the central Ural Mountains. Construction of the large nickel mining-metallurgical complex at Talnakh presumably progressed in 1975.

Osmiridium from gold ores (sales) [e]	2,800	2,500	2,400
U.S.S.R.: Placer platinum and platinum-group metals recovered from nickel-copper ores [e]	2,450,000	2,500,000	2,650,000
United States: Placer platinum and platinum-group metals from gold and copper ores	19,980	12,657	18,920
Total [3]	[r] 5,232,149	5,773,739	5,766,894

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Excludes metal refined in Norway and the United Kingdom derived from Canadian and South African ores.

[2] Japanese figures exclude metal recovered from Philippine ore.

[3] Total excludes metal refined in West Germany and which is believed to be derived from imported ores. Production was as follows: 1974—3,340 ounces; 1974—4,115 ounces; 1975—3,601 ounces.

TECHNOLOGY

Automotive emissions control catalysts, in which platinum or platinum-palladium were the active metals, were used on most of the new cars sold in the United States in 1975. By most accounts, they performed reliably and were free of some of the difficulties that had been feared, such as catastrophic overheating or rapid poisoning. In October, General Motors Corp. (GM) and the Environmental Protection Agency (EPA) conducted a joint study involving several hundred vehicles, driven simultaneously on the GM test track, to determine whether sulfate emissions generated by the catalysts could reach hazardous levels in adverse traffic density-weather conditions. The test showed that the likelihood of hazardous accumulation was considerably less than had been thought, even when all the vehicles were equipped with catalytic converters.[7] It was demonstrated in another study that the position of the converter in the exhaust train and its operating temperature both have an important influence on the degree of lead poisoning of the catalyst, especially when lead scavengers, such as ethylene dibromide, are used.[8] In another automotive development, a new platinum- or ruthenium-containing catalyst said to be compatible with leaded gasoline was reported.[9]

A Monsanto Chemical Co. plant came onstream using a new rhodium-based homogeneous catalyst for the synthesis of acetic acid from methanol and carbon monoxide.[10] Another rhodium-based catalyst for hydroformylation, or oxo, reactions was developed and will be used in three new plants being built by Union Carbide Corp.[11]

Bureau of Mines scientists in 1975 worked on the formation of platinum metal shapes by chemical vapor deposition, and the formation of heavy platinum coatings by electrodeposition from molten salt baths. Industry reported that coatings up to 0.006 inch (150 micrometers) thick can be plated from molten cyanide baths.[12]

The conventional method for metallization of glass involves dipping in an acidic stannous chloride solution, then in an acidic palladium chloride solution, and finally in an electroless nickel plating bath. Tin ions are absorbed on the glass surface and then displaced galvanically by palladium ions, which nucleate nickel deposition. It was reported that a more strongly adherent nickel film could be formed by electroless plating onto palladium ions which had been injected into the glass surface from a glow discharge.[13] It was also reported that stress-free, adherent films of platinum could be deposited on gallium arsenide crystals, used in certain high-power microwave devices, by radiofrequency sputtering.[14]

Electrically conductive thick films, made by screen printing a paste of silver-palladium alloy powder mixed with glass onto a ceramic substrate and then firing the assembly, are widely used in hybrid microelectronic circuits. Leadout wires are readily soldered to the silver-palladium-glass conductors, but prolonged use at operating temperatures leads to drastic weakening of the attachments and thus to circuit failure. A study of the problem led to a new paste formulation and manufacturing method which resulted in substantial improvement in adherence of aged films.[15] Also, a new thick-film platinum resistance thermometer was developed that is mechanically stronger and cheaper than conventional resistance thermometers.

A process for manufacturing submicrometer-thick palladium flakes was described. These are potentially useful for the solid storage of hydrogen.[16]

Potash

By Richard H. Singleton [1]

Domestic potash production dropped 2% to 2.5 million short tons of K_2O equivalent in 1975; this was the third successive year of slight decline. Total value increased 40% over that of 1974. Apparent consumption decreased 17% to 5.1 million tons of K_2O because of reduced demand for fertilizer at the farm level. Domestic producers stockpiled 16% of their production and their total stockpiles nearly tripled to 0.6 million tons of K_2O at yearend. Exports for fertilizer use decreased 2% remaining near 0.8 million tons of K_2O. Imports for fertilizer use, approximately 95% from Canada, decreased 14% to 3.7 million tons of K_2O but still accounted for 64% of domestic potash deliveries.

Disagreement continued in the Canadian Province of Saskatchewan between the provincial government and private industry regarding production and marketing of potash. The industry filed suit on the constitutionality of the reserves tax. Legislaion was passed by the provincial government in January 1976, enabling them to acquire 50% or more of the potash industry in the province. Although Canadian production of potash, all in Saskatchewan, remained the same, at 6.0 million tons of K_2O, producers' inventories increased by a factor of 8 to 1.0 million tons of K_2O at yearend.

Potash production as well as mine and plant capacity continued to increase in the U.S.S.R. Production in the centrally planned economy countries reportedly increased 4% to 12.4 million tons of K_2O. Production in Western Europe decreased 10% to 5.4 million tons of K_2O. Jordan announced plans for construction of a large plant to recover potash from Dead Sea brines. An extensive potash deposit was discovered in Laos. Full production at the large, new mine in Yorkshire, England, was delayed because of technical difficulties. Exploitation of potash deposits in Brazil was postponed because of the presence of petroleum activities in the same area.

ʳ Revised.
[1] Excludes potassium chemicals and mixed fertilizers.
[2] Measured by sales plus imports.
[3] Measured by deliveries minus exports.

DOMESTIC PRODUCTION

Production of marketable potash salts, in terms of K_2O content, declined 2% in 1975 compared with 1974 output. The value of production increased 40%, however, in a continuation of last year's price rise. Costs of production at potash mines were affected by the general rise in price levels, particularly for fuel, power, and explosives. Eighty percent of U.S. production was as potassium chloride and 10% was as potassium sulfate.

Potash sales by domestic producers equaled 36% of deliveries in 1975 compared with 37% in 1974. The remaining 64% of 1975 deliveries were met by imports.

In New Mexico, source of 83% of U.S. production in 1975, eight underground mines were operated near Carlsbad by AMAX Chemical Corp., Duval Corp., International Minerals & Chemical Corp., Kerr-McGee Chemical Corp., Mississippi Chemical Corp., National Potash Co., and Potash Co. of America.

The following three companies produced potash in Utah: Texasgulf, Inc., working an underground mine near Moab by solution mining; Great Salt Lake Minerals & Chemicals Corp., producing potassium sulfate from brines of the Great Salt Lake; and Kaiser Aluminum & Chemical Corp., treating natural surface brines near Wendover.

In California, potash continued to be produced from Searles Lake brines by the Kerr-McGee Chemical Corp.

[3] Data do not add to total shown bceause of independent rounding.

The potash (K_2O) content of ores mined in New Mexico declined to 15.2% in 1975 from 15.5% in 1974. These ores had contained 18.0% K_2O in 1964.

In 1975 Mississippi Chemical Corp. opened a mine previously owned by Teledyne. It had been closed in 1973 and purchased from Teledyne in 1974. Previous plans to construct a new processing facility were abandoned; instead, plans were announced in May to modernize the old facility including installation of new flotation cells. Estimated planned output of the modernized facility was 170,000 tons of K_2O equivalent per year.

Duval Corp. increased muriate of potash production capacity at Carlsbad in late 1975 through acquisition and equipment of a new mine.

A planned expansion by International Minerals & Chemical Corp. at Carlsbad, which had begun in 1974, was terminated in 1975.

A sweeping investigation of the fertilizer industry was launched early in 1975 by a Federal grand jury in Chicago, Ill., to determine whether there had been any price fixing or other antitrust violations in either domestic or foreign operations.

A preliminary report[2] dealing with the present and projected environmental impact of potash mining and beneficiation on public lands in New Mexico was issued by the Bureau of Land Management. Public meetings were scheduled for early 1976 for discussions on these matters with an intention of subsequently issuing a final report.

Exploratory drillings were made 30 miles east of Carlsbad, N. Mex., in behalf of the Energy Research and Development Administration (ERDA) to investigate the salt beds in that area as a potential underground site for disposal of radioactive waste products. It was estimated that use of this contemplated storage site would effectively eliminate about 8% of the potash resources in New Mexico.[3]

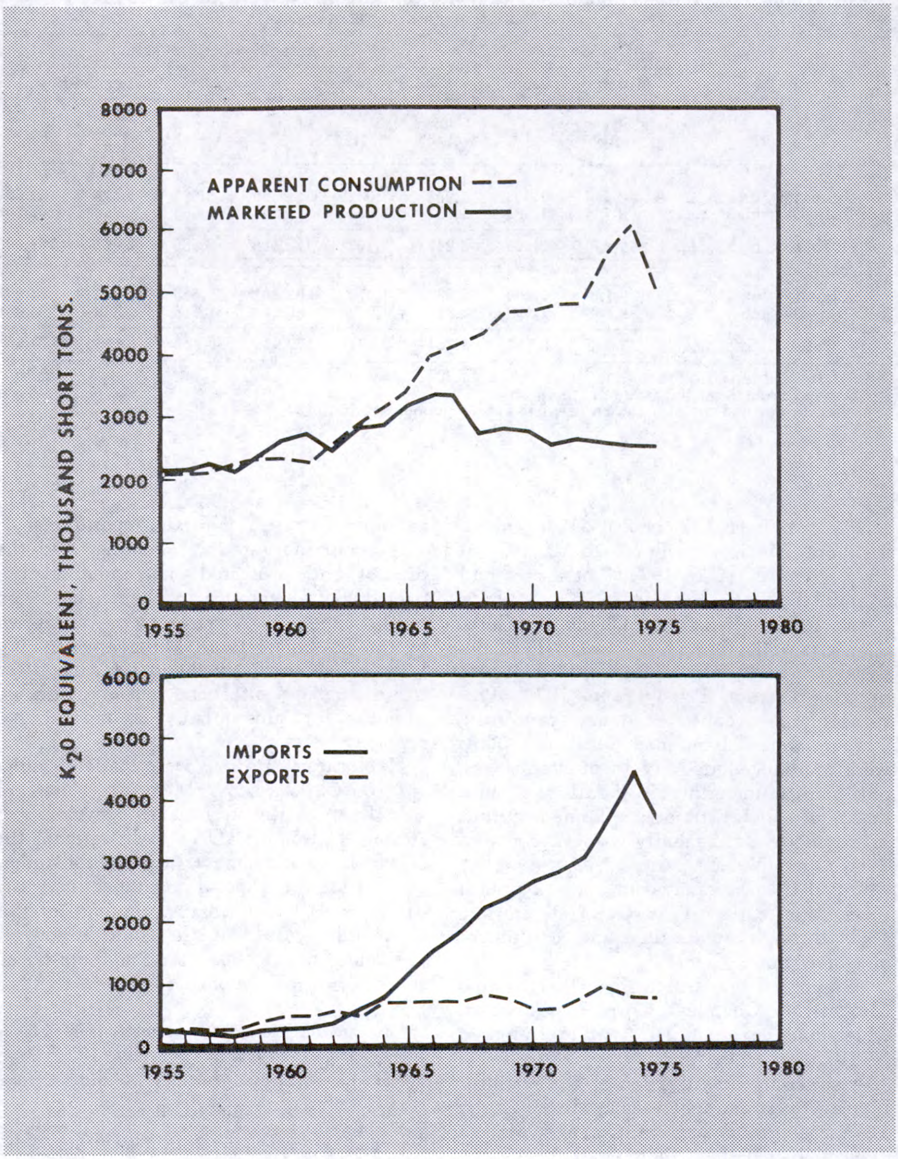

Figure 1.—Marketable production, apparent consumption, exports and imports of potassium salts measured in K_2O equivalent.

CONSUMPTION AND USES

Apparent domestic consumption of potash decreased 17% to 5.1 million tons of K_2O; approximately 94% of this was used in the fertilizer industry and the balance in chemicals manufacture. The north-central States of Illinois, Indiana, Iowa, Minnesota, and Ohio purchased 47% of all agricultural potash. Leading consumers of chemical potash were New York (22%), Alabama (16%), Illinois (14%), and Ohio (13%). Ninety-two percent of domestic raw potash was consumed as potassium chloride and 3% was consumed as potassium sulfate.

STOCKS

Domestic producers stockpiled 16% of their production in 1975 because of reduced demand, mainly because of resistance to higher prices on the farm level; similar stockpiling in 1974 had been less than 1%. Canadian producers' stocks at both onsite and offsite locations increased considerably during 1975—from 132,000 tons of K_2O at yearend 1974, to 1,091,000 tons at yearend 1975.

Table 5.—Yearend stocks of marketable potassium salts in the United States
(Thousand short tons)

Year	Number of producers	Stocks, Dec. 31

1973	11	388	206
1974	10	394	211
1975	11	1,152	619

PRICES

Prices continued an upward trend during 1975, although not as sharply as during 1974 when potassium muriate prices increased by approximately 50%. Canadian prices, f.o.b. mine, for muriate of potash remained at a few dollars per ton less than U.S. prices.

FOREIGN TRADE

About 14% of U.S. potash deliveries were exported in 1975 as fertilizer, 80% of which was muriate of potash and the balance mainly sulfate; total tonnage was not significantly different from that exported in 1974. In addition about 1% was exported as chemicals; this represented nearly triple that exported as chemicals in 1974 with most of the increase going to Brazil.

Potash imports decreased 14% but still accounted for 64% of domestic potash deliveries; approximately 95% of these imports were from Canada. Muriate of potash comprised 98% of the imports. The second-place supplier, Israel, provided a little over 2% of U.S. imports in 1975. Imports of potash from the Congo began, and it became the third-place supplier providing about 1% of U.S. imports in 1975.

r Revised.

[1] Less than ½ unit.

WORLD REVIEW

Australia.—The Texada Mines, Pty. Ltd.'s potash refinery at Lake McLeod in Western Australia was placed on standby in September because the planned Southeast Asian market never developed. There were no immediate plans to reopen the facility.

Brazil.—Exploitation of the Sergipe potash deposits remained stalled because of objections by Petróleo Brasileiro S.A., a 50% participant in the project, that the proposed solution mining methods would interfere with petroleum activities in the area. Brazil is completely dependent on imports for its potash supply.

Canada.—Annual production, all in Saskatchewan, remained near 6 million tons of K_2O equivalent in 1975 although production at several mines was interrupted by either strikes or fires. Over 80% of production was exported, mostly to the United States. Yearend inventories increased from 132,000 tons in 1974 to 1,091,000 tons in 1975 as a result of decreased demand. Only 5% of production was used domestically.

The Canadian Potash Producers Association filed suit in Saskatchewan provincial court in Regina maintaining that both the reserves tax and the prorationing fee on potash are unconstitutional or illegal. The Saskatchewan Government decided to oppose this up to the Canadian Supreme Court, if necessary, and litigation possibly lasting up to 3 years was indicated. At yearend, most producing companies were behind in payments of the reserves tax. Industry claimed that the reserves tax equaled one-quarter to one-half of pretax profits. Planned expansions in capacity, claimed by industry to have totaled $200 million, were deferred or cancelled in opposition to the expressed wishes of the Saskatchewan Government.

The Saskatchewan Government announced in November that it would seek to acquire some or all of the producing potash mines in that Province, a majority of which are U.S. owned and that if agreement with the owners on terms of sale was not reached, the Province would expropriate the properties. Enabling legislation was passed by the Saskatchewan Legislature in January 1976. The necessary funds were being sought actively by the Premier of Saskatchewan.

An agreement was signed in January 1976 by the Province of New Brunswick and International Minerals & Chemical Corp. (Canada) Ltd. granting that corporation the rights to explore and develop a potash and salt prospect near Salt Springs in Kings County in southern New Brunswick. A 3,000-foot drill hole at Salt Springs intersected 51 feet of potash containing an average of 31.6% K_2O near the 2,000-foot depth; this was underlain by salt averaging more than 98% NaCl. The corporation was committed to spend a minimum of $1 million on an approved exploration program during the initial phase of work.

The Potash Co. of America continued drilling in 1975 on its Sussex potash-salt property in New Brunswick and was the only other private firm conducting potash exploration in that Province. A total of 21 holes had been drilled by yearend and the company was seeking an agreement with the New Brunswick Government to permit further exploration.

Chile.—Sociedad Química y Minera de Chile, S.A., announced that its production of potassium nitrate would be increased to approximately 40,000 short tons of K_2O equivalent per year. A joint Chilean-U.S. team continued examining lithium-potassium deposits in northern Chile.

France.—A lack of agreement existed among Western European countries concerning reduction of industrial pollution of the Rhine River. Approximately one-third of chloride pollution in the Rhine comes from salt-dumping actions of the French potash mines. France withdrew in 1975 from a multination cost-sharing proposal involving West Germany, Switzerland, and the Netherlands on the basis that it was too costly. Legal action seeking damages by a Netherlander citizens' group was rejected in a Rotterdam court.

Italy.—After acquiring controlling interest in the potash mines of Sicily, the only producing units in Italy, the Sicilian government continued to operate the mines at low productivity and at about two-thirds capacity because of a lack of managerial and technical talent and a lack of employee incentive, although much of the equipment was quite modern. A plan was presented to the Sicilian government for a national government-controlled agency to acquire control of the Sicilian potash industry from the Sicilian government.

Jordan.—The Arab Potash Company of Jordan announced plans for a $200 million project to recover at least 1 million tons per year of potash from the Dead Sea. The first processing step will be solar evaporative recrystallization in a series of ponds with a total area of 34 square miles. The planned completion date for the separation plant was 1981. The pilot project received financial aid in July from the International Development Association.

Laos.—Deposits of sylvite, reportedly containing at least 1 million tons of K_2O equivalent, were found north and east of Vientiane near the Thailand border. Test drillings made about 10 miles north of Vientiane located a bed approximately 100 feet thick described as a crystalline intergrowth of sylvite and halite assaying around 30% K_2O. Development of this resource, which would require large investment in transportation as well as mining and beneficiation facilities, could create a major supply of potash for the Asian market. Much more drilling is required to estimate the magnitude of this resource.

Mexico.—Plans were announced by Guanos y Fertilizantes de Mexico S.A. to construct, by late 1976, an approximately 20,000-ton-per-year plant at Salamanca to treat alunite ore. The plant will use a process developed by the Guanajuato University whereby alunite is ammoniated to yield potassium and ammonium sulfates in solution and a hydrated alumina residue.

Netherlands.—Royal Dutch Shell announced plans to exploit the large underground salt deposits at Veendam in the north of the Netherlands. A trial quantity of crude brine containing potassium and magnesium salts was produced from the deposits and experiments were begun to develop a separation method.

Spain.—Potash reserves of Potassa de Navarra, the State-owned potash producer in northern Spain, were reportedly nearly exhausted and plans were announced to explore and develop new zones within a carnallite deposit near Pamplona. Planned production of beneficiated potash from this operation was 165,000 tons of K_2O per year by 1970.

One of the two privately owned potash producers, Minas de Potassa de Suria, announced plans to increase production by one-third to 220,000 tons of K_2O per year in 1980.

U.S.S.R.—Reported production of potash increased 18% compared with 1974. New potash mine and plant construction continued, particularly in the Uralkali Combine where two large mines, Berezniki no. 4 and Novosolikamsk, each with an annual capacity of about 3 million short tons of ore, were being built. Berezniki no. 3 came on-stream providing an additional U.S.S.R. capacity of 350,000 tons of K_2O. Performance of the industry was reportedly impaired by lack of sufficient transport to move the product from the mines.

Approximately 32% of the potash produced in the U.S.S.R. was exported—about 65% to centrally controlled economy countries (mainly Poland); about 20% to Western Europe (mainly Belgium-Luxembourg); about 10% to Asia and Oceania (mainly Japan); and about 5% to other countries.

United Kingdom.—Essential construction of mine and plant by Cleveland Potash, Ltd., at Boulby, Yorkshire, was completed and commercial operation began on a limited basis. Reported 1975 production was 37,000 tons of K_2O equivalent. Considerable mining development was required before full capacity, 550,000 tons of K_2O per year, expected by the end of 1976, could be reached. The sylvite ore contains an average of 25% K_2O and estimated reserves are approximately 100 million tons of K_2O equivalent. The ore contains some clay which may cause problems during froth flotation beneficiation.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Australia produced small, unreported quantities of marketable potash in 1974 and 1975 from newly developed facilities.

[2] Series revised to show actual production; previous editions have provided shipment statistics.

[3] Data for year ending June 30 of that stated as reported in the British Sulphur Corp. Ltd., Statistical Supplement No.12, November-December 1975, London, pp. 18–19.

[4] April 1 through March 31 (the year is offset by 3 months).

TECHNOLOGY

Experimental studies by the Bureau of Mines on the insoluble fines problem inherent in Carlsbad potash ores revealed that about 87% of the insoluble fines can be removed by selective flocculation prior to froth flotation. The crude ores contained about 16% K_2O and 3% clay fines. The subsequent flotation yielded a 55% K_2O concentrate containing less than 0.5% insolubles with an 86% K_2O recovery.

The Great Salt Lake Minerals & Chemicals Corp. engineered a Bureau of Mines-developed froth flotation process to concentrate low-grade potash solar evaporites from Great Salt Lake brines through the pilot plant stage, and constructed a commercial flotation plant with a capacity of 6 tons of K_2O equivalent per hour of potassium sulfate product.

Calculations indicate that potassium seed requirements for possible commercial magnetohydrodynamic electrical generation by the year 2000 will not have a major impact on the potash industry. Assuming operation in the year 2000 of 100 power station units, an optimistic projection, each generating 2,000 megawatts and with an assumed potassium seed loss of 2%, the calculated total seed loss is about 300,000 tons per year of K_2O equivalent; this is less than 3% of projected total domestic potash consumption in the year 2000. This calculated seed loss is about 0.2% of K_2O equivalent per ton of coal burned.

Studies made[4] by Hazen Research, Inc., under a U.S. Bureau of Mines contract on muriate of potash recoverability from geothermal brines in the Imperial Valley in southern California indicated economic feasibility but only if recovered as a coproduct. These brines contain up to about 2% K_2O and represent a significant potash resource.

Pumice and Volcanic Cinder

By Arthur C. Meisinger[1]

Total U.S. production of pumiceous materials in 1975 was the third largest in quantity (3.89 million tons) and the highest in value ($11.2 million) in history. Average values for crude and prepared material in 1975 increased 19% and 17%, respectively, over values reported in 1974. Higher prices as well as continued inflationary costs, particularly for volcanic cinder sold or used, for all major end uses except landscaping, contributed significantly to the increased value of domestic production.

Oregon led all producing States in 1975 with a record high production of 1.47 million tons, valued at a record high of $3.9 million; the State also led in the number of active operations with 86. The combined output of Arizona and Oregon accounted for 60% of total domestic output.

The combined use of pumiceous materials for road construction and concrete admixtures and aggregate accounted for 84% of U.S. consumption (excluding imports) compared with 82% in 1974.

U.S. exports of pumice and pumicite decreased 57% in quantity and 15% in value from those of 1974. The principal export destination for pumice in 1975 was West Germany, followed by Canada and 13 other countries. Imports of pumice declined drastically below those of 1974. Decreases of 50% in quantity and 65% in value for imported pumice generally reflected the slump in construction activity in 1975, particularly for concrete masonry products using pumice. Greece and Italy continued to be the major import sources of pumice for the United States.

DOMESTIC PRODUCTION

The quantity of pumiceous materials (pumice, pumicite, volcanic cinder, and scoria) produced in the United States in 1975 was 3.89 million tons, or only 1.1% under the 1974 figure of 3.94 million tons. However, the value of domestic production increased nearly 23% from $9.1 million in 1974 to a record high of $11.2 million. Inflationary costs and substantial price increases by producers of volcanic cinder contributed largely to the overall increase in the total value of pumiceous materials in 1975.

The quantity of pumice and pumicite produced in 1975 declined for the first time in 4 years, from 873,000 tons in 1974 to 790,000 tons, and value of production was $3.5 million compared with $3.7 million in 1974. Production of volcanic cinder and scoria increased in both quantity and value compared with that in 1974. Volcanic cinder and scoria comprised 80% of the domestic output of pumiceous materials compared with 78% in 1974.

Domestic output in 1975 came from 91 individuals, firms, and governmental agencies producing from 267 operations in 11 States, compared with 92 producers and 289 operations in 12 States in 1974. Oregon led all the producing States in number of active operations with 86, followed by California with 75, and Arizona with 47.

The combined output of pumiceous materials (primarily volcanic cinder) in Oregon and Arizona in 1975 was 2.3

---

[1] Industry economist, Division of Nonmetallic Minerals.

million tons, or 60% of the national total. Oregon's output was a record 1.47 million tons valued at $3.94 million, and was attributed to increased use of volcanic cinder for road construction and maintenance in National Forest lands throughout the State during the year.

Other States with significant output of pumiceous materials in 1975 were New Mexico, 397,000 tons; California, 348,000 tons; and Hawaii, 318,000 tons. Volcanic cinder (including scoria) was produced in nine of the eleven States and in American Samoa.

CONSUMPTION AND USES

The combined use of pumiceous materials for road construction and concrete admixtures and aggregate accounted for 84% of U.S. consumption compared with 82% in 1974. In 1975, landscaping use comprised 4%; railroad ballast, 8%; and abrasives and other uses, 4%. Compared with consumption in 1974, pumiceous materials used in landscaping increased nearly 48% and that used in road construction, about 10%. However, use in concrete admixture and aggregate in 1975 declined 10%; in railroad ballast, 26%; in abrasives, 47%; and in other uses, 27%.

[1] Includes absorbents, heat-or-cold insulating medium, roofing granules, soil conditioners, and miscellaneous uses.

[2] Data may not add to totals shown because of independent rounding.

PRICES

The weighted average value for pumiceous materials produced domestically in 1975 was $2.88 per ton compared with $2.32 per ton in 1974. The average value for crude pumice, pumicite, and volcanic cinder sold and used by producers increased 19% from $1.10 per ton in 1974 to $1.31 per ton, and the average value for prepared material rose 17% from $3.72 per ton to $4.36 per ton.

Increases in average prices for all major end uses of pumiceous materials (except landscaping) were reported in 1975. Compared with prices in 1974, the average price per ton for pumice and volcanic cinder used in abrasives, including cleaning and scouring compounds, was $60.78, a $29.78 increase; for concrete admixtures and aggregate, $2.87, a $0.25 increase; for railroad ballast, $1.47, a $0.37 increase; for road construction, $2.16, a $0.85 increase; and for other uses, $7.99, a $1.59 increase. The average price for landscaping decreased $2.31 per ton from $9.97 in 1974 to $7.66 in 1975.

No changes were reported in price quotations for pumice by trade publications in 1975. Quoted prices in American Paint and Coatings Journal at yearend, per pound, bagged f.o.b. New York or Chicago, were powdered, $0.0445 to $0.08; and lump, $0.0665 to $0.09. Quoted prices in Chemical Marketing Reporter at yearend were as follows for domestic grades, bagged in 1-ton lots: Fine, $0.0765 to $0.1140 per pound; medium, $0.1160 per pound; and coarse, $0.094 per pound. Prices from the same source for imported (Italian) silk-screened, pumice bagged in 1-ton lots, were as follows: Fine, $138 per ton; medium, $150 per ton; and coarse, $140 per ton. The price of imported small and large lump was quoted at $275 per ton.

FOREIGN TRADE

Exports of pumice and pumicite totaled 1,252 tons valued at slightly more than $1 million in 1975, compared with 2,911 tons and $1.2 million in 1974, a decrease of 57% in quantity, but only 15% for the value. Pumice shipments were made to 15 countries, of which West Germany received 729 tons (58%); Canada, 334 tons (27%); and the remaining countries, 189 tons, (15%).

The quantity and value of pumice imports for consumption decreased significantly from that of 1974. The quantity decrease was 50% in 1975, or 147,500 tons less than in 1974, and the value of imports declined 65%, or nearly $1 million less than in 1974. All import classes showed declines in 1975; crude or unmanufactured (61%), wholly or partly manufactured (69%), manufacture of concrete masonry products (50%), and manufactured products, n.s.p.f., value (5%).

Pumice stone, TSUS No. 519.05, for use in concrete products, continued to be admitted into the United States duty free. Duties (unchanged from 1974) for other pumice products at yearend were as follows: TSUS No. 519.11, crude or crushed, valued not over $15 per ton, 0.02 cent per pound; TSUS No. 519.14, crude or crushed, valued over $15 per ton, 0.04 cent per pound; TSUS No. 519.31, in grains or ground, pulverized or refined, 0.17 cent per pound; and TSUS No. 519.93 millstones, abrasive wheels, and abrasive articles, n.s.p.f., and 523.61 articles, n.s.p.f., 7% ad valorem.

Rare-Earth Minerals and Metals

By Rebecca P. Smith [1]

Production of rare-earth oxide (REO) contained in bastnäsite and monazite concentrates decreased 23% in 1975, reflecting the low demand for rare earths in most industries. However, some applications using rare earths increased, notably X-ray phosphors for intensifying screen images and rare-earth-cobalt permanent magnets. Despite these changes, the overall end-use consumption pattern was similar to that of 1974. Petroleum catalysts continued to be the major consumer, with metallurgical applications second. The ceramic and glass industry was another major consumer.

Molycorp Inc., and the Davison Div. of W. R. Grace & Co. continued to be the major processors of rare-earth minerals. Production of rare-earth compounds and metals was adequate to meet market demand. There was a general increase in stocks during the year, and many rare-earth companies were not operating at full capacity near the end of 1975.

U.S. exports of rare-earth concentrates, compounds and metals declined in 1975. Imports of REO, mainly in the form of monazite, increased significantly. The major supplying countries for monazite were Malaysia and Thailand; for compounds and metals, Austria, Brazil, France, Japan, West Germany, and the United Kingdom; and for yttrium concentrate, Canada.

Legislation and Government Programs.—At the end of 1975, 7,398 tons (dry) of REO equivalent was held in the General Services Administration (GSA) stockpile. Disposals for the year totaled 1,050 tons of contained REO. Government stocks of yttrium oxide (Y_2O_3) remained unchanged at 237 pounds.

DOMESTIC PRODUCTION

Concentrate.—Domestic production of REO in bastnäsite and monazite concentrates decreased about 23% in 1975 from the record high of 1974. Production in 1975 was also below the high level in 1973, but was higher than in previous years. Bastnäsite continued to be the major source of rare earths, the remainder, less than 10%, was produced from monazite.

According to Molycorp's annual report, its Mountain Pass, Calif., operation produced 16,500 tons of REO contained in bastnäsite concentrate during 1975; 1974 production was 21,950 tons.

Titanium Enterprises, owned jointly by American Cyanamid Co. and Union Camp Corp., continued to recover monazite as a byproduct of mining a beach sand deposit near Green Cove Springs, Fla., for titanium minerals and zircon. During 1975, monazite production remained at the 1974 level.

The only other domestic producer of monazite was Humphreys Mining Co. Again the monazite was recovered as a byproduct of mining heavy-mineral beach sand. The dredging operation was located near Hilliard, Fla., and the wet heavy concentrates were trucked to the company dry plant at Folkston, Ga., for processing. Monazite production increased about 13% over that of 1974, which was abnormally low because the dredging operations were relocated.

Buttes Gas & Oil Co. were conducting feasibility studies on a large deposit of titanium in southwestern Colorado. The deposit was reported to contain significant amounts of rare-earth elements that could be recovered during processing for titanium.

---

[1] Physical scientist, Division of Nonferrous Metals.

Compounds and Metals.—In 1975, there were only two major processors and producers of rare-earth compounds, Molycorp and the Davison Div. of W. R. Grace & Co., Chattanooga, Tenn. Molycorp, with processing plants at Mountain Pass, Calif., Louviers, Colo., and York, Pa., continued to be the principal domestic producer. Molycorp's production declined, compared with 1974 production, and sales were also down, $18.9 million compared with $23.1 million in 1974.

A 3-year program to expand mill and chemical-plant production capacities at Mountain Pass was completed at a cost of about $7 million. The new facilities are expected to be operational in 1976. The new capacities of the mill and chemical plant were 60 million and 30 million pounds of rare-earth oxide, respectively.[2]

Producers of high-purity rare-earth oxides and compounds were Molycorp; W. R. Grace; Nucor Corp., Research Chemicals Div., Phoenix, Ariz.; Atomergic Chemetals Corp., Plainview, N.Y.; and Transelco Inc., Penn Yan, N.Y. In addition, high-purity rare-earth compounds and metals were also sold from the remaining stocks held by a former rare-earth processor, Michigan Chemical Corp., St. Louis, Mich.

Mischmetal production during 1975 was about the same as that in 1974; however, shipments were down. The three domestic companies that produced mischmetal during 1975 were Ronson Metals Corp., Newark, N.J.; Reactive Metals and Alloys Corp. (REMACOR), West Pittsburgh, Pa.; and Rare Earth Metals Co. of America (REMCOA), owned jointly by Aluminum Co. of America and Molycorp, Arnold, Pa. REMACOR was formed from the former Rare Earth Industries and began mischmetal production in March. REMCOA started production of mischmetal from its 125-ton-per-year demonstration unit during the fourth quarter.

Rare-earth-ferrosilicon alloys were produced by three companies: Foote Mineral Company, Exton, Pa.; Ohio Ferro-Alloys Corp., Canton, Ohio; and Union Carbide Corp., Alloy, W. Va.

Nucor was the major producer of high-purity rare-earth metals; the predominate producer of yttrium compounds was Molycorp. The yttrium was processed from yttrium-rare-earth concentrates imported from Canada.

CONSUMPTION AND USES

Domestic rare-earth processors consumed an estimated 12,600 tons of REO contained in raw materials in 1975. Consumption of bastnäsite and monazite decreased 32% and 41%, respectively, from that of 1974. Shipments of rare-earth and yttrium products from processing plants to domestic end-use consumers were about 7,500 tons of contained REO, valued at about $28 million.

The approximate quantitative percentage distribution of rare-earth and yttrium consumption by end-use, based on information supplied by primary processors and certain consumers, was as follows: Petroleum cracking catalysts, 45%; metallurgical, including nodular iron and steel, other alloys, and mischmetal, 33%; ceramics and glass, 16%; and miscellaneous, including electrical, arc carbons, and research, 6%. Shipments of high-purity rare-earth and yttrium oxides and metals, although accounting for about 28% of value shipped, represented less than 1% of the total weight of shipments.

The use of rare-earth zeolites in cracking catalysts to increase gasoline yields from petroleum feedstocks continued to be the single largest use of rare earths. Metallurgical usage of rare-earth metals, mostly as additives to ductile iron and steel, declined slightly. This was a result of low demand for high-strength low-alloy steels (especially in arctic pipeline), and from delays in expansion of these steels into the automobile industry for weight reduction. Rare earths are added mostly as mischmetal or rare-earth silicides. Beginning in 1975, ferrosilicon-mischmetal alloy containing 50% mischmetal was available. In previous years, alloys of 30% to 35% mischmetal were common. Mischmetal in customized ingot canisters weighing up to 650 pounds was available for the first time for plunging into molten steel ladles. Another new development was ductile mischmetal wire available for automatic continuous feed into molten steel.

---

[2] Molycorp Inc. 1975 Annual Report. P. 5.

The production of lighter and striker flints continued to be a major consumer of mischmetal. Other rare-earth alloys and metals were used in the production of high-temperature alloys and superalloys.

The glass industry continued to be a major consumer of rare-earth compounds, particularly cerium oxide. The established uses of cerium oxide are as an abrasive for polishing plate glass; an additive in eyeglasses, television tubes, and camera lenses; and as a decolorizing agent in refining clear glass. Other rare-earth oxides—praseodymium, erbium, holmium, and neodymium—were used as colorants in glass. Lanthanum oxide was used to improve the refractive quality of camera lenses.

The use of rare-earth elements in X-ray phosphors increased about 250% in 1975. Terbium-activated gadolinium or lanthanum oxysulfide phosphors were used to intensify X-ray screen images. Because of the effectiveness of these phosphors, they allowed faster exposure of X-ray film, which reduced patient X-ray dosages as much as 80%. In 1975, an estimated 40,000 pounds of REO in phosphors was consumed; in 1974, consumption was 16,000 pounds.[3]

Yttrium and europium oxide were consumed as key constituents of the red phosphor in color television tubes.

Crystals of yttrium (or gadolinium)—aluminum (or iron) garnet were used as microwave filters and control devices, as simulated diamonds and, when doped with neodymium or erbium, as lasers. Minor quantities of gadolinium-gallium garnet in thin-film, magnetic bubbles were used in communication and computer systems.

Significant quantities of rare-earth oxides and fluorides were used in carbon-arc lamps, which emit a high-intensity white light, used in searchlights and color motion picture lights.

The consumption of rare-earth-cobalt alloys in permanent magnets continued to expand. These high-energy magnets, which are two to three times more powerful than conventional permanent magnets, are used mainly in small electric motors and generators, electric wristwatches, and electronic tubes. Samarium and mischmetal predominated as the rare-earth elements alloyed with cobalt.

STOCKS

At yearend 1975, bastnäsite stocks held by the principal producer and four other chemical processors increased 176% compared with those at the beginning of the year. Monazite stocks held by the two producers and two processing companies increased 68% during the year. Stocks of rare-earth compounds and mixtures generally increased during the year. Mischmetal stocks held by the three producers remained steady. Stocks of high-purity metals held by six companies decreased 70% in 1975.

PRICES

Prices for domestic monazite during 1975 were similar to 1974 prices. The average declared value of imported monazite from Malaysia and Thailand increased from $152 per short ton in 1974 to $207 per short ton in 1975. The average price per short ton of Australian monazite (minimum 60% REO plus ThO_2) as quoted in Metal Bulletin (London) remained constant during 1975 at $203. Quoted prices for Malaysian xenotime concentrate containing a minimum 25% Y_2O_3 decreased in 1975 to $2 to $3 per pound c.i.f. from $3 to $5 in 1974.

Prices for unleached, leached, and calcined bastnäsite containing 55% to 60%, 68% to 72%, and 85% to 90% REO, respectively, were increased on March 1, 1975, from 36, 41, and 48 cents per pound REO, to 45, 50, 60 cents, respectively. Prices quoted were f.o.b. Mountain Pass or Nipton, Calif., in 100-pound paper bags or 55-gallon steel drums in truckload or carload lots.

Prices of rare-earth compounds increased for many products during 1975, reflecting the increased price of the concentrate and rising production cost. Most prices of rare-earth products are negotiable if purchased in large quantities. A sampling of quoted prices at yearend of rare-earth compounds, per pound f.o.b. plant, were as follows: Lanthanum—rare-earth hydrate, 75% REO, $0.75; rare-earth chloride, 46% REO, $0.50; rare-earth carbonate, 65% REO, $1.30; and cerium fluoride, 62% REO, $1.25.

---

[3] The Northern Miner (Canada). Rare-Earth Application for X-rays Increases. V. 61, No. 46, Jan. 29, 1976, p. 12.

Quotations on cerium hydrate, 90% CeO_2 of total REO, increased to $2.65 per pound of contained oxide for a minimum of 7,500 pounds from $2.15 in 1974.

Prices quoted in the American Metal Market for 1-pound ingots in 50- to 100-pound lots of 97% didymium, and cerium-free mischmetal were $15 and $12, respectively, f.o.b. plant. Compared with 1974 prices, the price of didymium remained stable, but that of cerium-free mischmetal increased $7 per pound. Mischmetal of 99.8% purity was quoted at $3.45 per pound same basis, an increase of $0.20 from 1974. Quoted prices of rare-earth metals for magnet use remained at the 1974 levels: Cerium, $18; lanthanum, $27.50; praseodymium, $62.50; and samarium, $75 (all 99% purity and in 10- to 100-pound amounts).

Table 1.—Prices of high-purity rare-earth oxides, salts, and metals in 1975 [1]

(Dollars per pound)

Element	Oxide [2]	Salts [3]	Metal [4]
Cerium	6.50	12.00	50.00

[1] Research Chemicals, Nucor Corp., f.o.b. Phoenix, Ariz. For large quantities, prices may be negotiable. Other producers may have different prices on some items.

[2] Minimum 99.9% purity, more than 1 pound.

[3] Minimum 99.9% purity, more than 1 pound; includes chlorides, nitrates, sulfates, oxalates, and acetates.

[4] Minimum 1 pound, ingot form.

FOREIGN TRADE

Exports of bastnäsite concentrates contained about 3,400 tons of REO, according to the sole producer, Molycorp. This was substantially down from the 4,700 tons exported in 1974. Exports of ferrocerium and other pyrophoric alloys to Canada, the Netherlands, and 23 other countries decreased 48% to 100,279 pounds valued at $299,994. The average unit value was $2.99 per pound. Shipments of compounds and mixtures of rare-earth metals, including yttrium and scandium, went to 27 countries. West Germany and Austria received about 65% of the shipments, which totaled 1,465,364 pounds valued at $2,719,918. This was a 71% decrease in shipments from 1974.

Monazite imports (table 2), mostly from Malaysia, increased to 2,565 tons with an average unit value of $207 per short ton. Imports of cerium oxide, predominately from France, declined to 624 pounds valued at $5,216 in 1975 compared with 31,390 pounds valued at $100,977 in 1974. The average unit value increased 61% to $8.36 per pound. Imports of cerium salts and cerium ore from the United Kingdom totaled 9,600 and 2,139 pounds, respectively, with an average unit price of $1.01 and $10.61 per pound, respectively. Imports of other cerium compounds, predominately from France, totaled 6,189 pounds valued at $28,975. The unit value ranged from $3.46 (France) to $66.02 (Switzerland) per pound.

Imports of rare-earth metals, scandium, and yttrium totaled 3,207 pounds valued at $87,818. The major supplier was the U.S.S.R. with 2,659 pounds valued at $58,336.

Imports of ferrocerium and other pyrophoric alloys decreased 41% to 33,852 pounds valued at $186,640. France supplied 65% of the total valued at $112,287, followed by Japan with 31% valued at $65,053. Other suppliers were the United Kingdom, Austria, West Germany, and Singapore. Imports of rare-earth metals and alloys, predominately from the United Kingdom and Brazil, increased 56% to 19,518 pounds valued at $111,857. The average unit value decreased from $22.64 per pound in 1974 to $5.73 per pound in 1975 owing to increased mischmetal imports from Brazil. Imports of other rare-earth metals, entirely from West Germany, totaled 22 pounds valued at $355.

WORLD REVIEW

Australia.—According to the Rutile & Zircon Development Assoc., Ltd., the 1975 production of monazite by member companies was as follows, in short tons:

State	1973	1974	1975
New South Wales	1,076	1,071	1,207
Queensland	64	30	685
Western Australia	3,087	2,550	3,253
Total	4,227	3,651	5,145

The 41% increase in 1975 production over that of 1974 reflected the coming onstream of the heavy mineral sands project of Allied Eneabba Pty., Ltd. The company mine and wet concentrator were located near Eneabba, Western Australia, and a dry separation plant was planned at Meru, the port of export.[4] Reserves in the Eneabba mineral field were estimated at 220,000 tons of monazite.

Other companies with an interest in the Eneabba mineral fields in Western Australia included Jennings Mining, Ltd., which was producing heavy minerals, and Western Titanium, Ltd., and Western Mining Corp. Ltd., Mineral Sands Pty., Ltd., which have planned projects in the area. International Nickel Australia, Ltd., a subsidiary of the International Nickel Co. of Canada, Ltd., filed an application to search for monazite and other related heavy minerals in the Eneabba area.[5]

Mary Kathleen Uranium, Ltd., announced plans to construct a large-scale pilot plant to recover rare earths from uranium-processing operations. The rare-earth recovery plant was expected to be completed in early 1976. Commercial production is dependent upon further investigation into the economic feasibility of marketing rare-earth compounds, and was expected to begin in 2 to 3 years. It was estimated that the sales of rare earths could amount to $4 million per year.[6]

[e] Estimate. [p] Preliminary. [r] Revised. W Withheld to avoid disclosing individual company confidential data.

[1] In addition to the countries listed, Indonesia and North Korea may produce monazite, but information is inadequate to make reliable estimates of output levels.

[2] Exports.

[3] Revised to zero.

Burundi.—A large vein of bastnäsite was reportedly found near the original rare-earth mining site at Gakara, about 25 miles south of Bujumbura.[7]

Canada.—Denison Mines, Ltd., reported production of 77,000 pounds of yttrium oxide contained in yttrium-rare-earth concentrate in 1975; all production was exported. This was an 11% decline in production from that in 1974, mainly a result of labor problems during 1975. Since the start of operations 17 years ago, a total of 625,000 pounds of yttrium oxide has been produced.[8]

Germany, West.—A new production process for rare-earth-cobalt alloy powders to make permanent magnets was developed by Th. Goldschmidt AG of Essen. The process was based on the calciothermic reduction of oxidic starting materials. In March, a new rare-earth alloy plant at Essen was brought into operation by Goldschmidt.[9]

India.—A monazite-sand separation plant at Gopalpur in southern Orissa was under construction by the Government-owned Indian Rare Earth, Ltd. Initial production of 4,400 tons of monazite per year, which will be a byproduct of ilmenite and rutile mining, was scheduled.[10]

India's National Institute of Oceanography conducted an extensive survey of shallow offshore areas for heavy minerals. According to the Institute, India's beaches were rich in heavy mineral placers containing ilmenite, monazite, and garnet.[11]

Japan.—A proposed expansion at the Sumitomo Special Metals Co. Yamasaki works to increase the capacity of its rare-earth-cobalt magnet plant was scheduled for spring 1976. The capacity was to be increased from 20 to 500 kilograms per month.[12]

Imports of crude rare-earth chloride declined from 2,157 tons in 1974 to 672 tons, of which 39 tons was imported from the United States. The demand for rare-earth materials declined in 1975, although specific compounds such as yttrium, europium, and lanthanum oxide for use in a ceramic condenser were in higher demand. The rare-earth compounds that declined in demand from the 1974 level were fluorides used in carbon arcs and the steel industry, mischmetal for the steel industry, cerium oxide for polishing optical glass, and lanthanum oxide used in optical glass.[13]

Liberia.—According to a cooperative study by the U.S. Geological Survey and the Liberian Geological Survey, Liberian coastal sands may contain sufficient monazite and other heavy minerals for profitable extraction. Analysis indicated that the monazite contained 59.9% REO.[14]

Malaysia.—Malaysian Rare Earth Corp. (MRE), a joint venture of Mitsubishi Chemical Industries Ltd. of Japan and Beh Minerals Sendirian Berhad of Ipoh, Perak State, Malaysia, was formed in February. MRE planned to produce over 11 tons per month of semiprocessed yttrium concentrate by June 1976. The source of the yttrium was the mineral xenotime, a byproduct of Malaysia's heavy-mineral mining.[15]

South Africa, Republic of.—The proposed heavy-mineral operation on the east coast, north of Richards Bay by two companies, Tisand (Pty.) Ltd. and Richards Bay Iron and Titanium (Pty.) Ltd. was scheduled to proceed as soon as financial arrangements were completed. The proposed mining area will be approximately 11 miles long by 2 miles wide. Monazite will probably be recovered as a byproduct of ilmenite, rutile and zircon mining. Output was expected to be 75,000 tons of rutile and 150,000 tons of zircon per year.[16]

Sri Lanka.—Work continued at Pulmoddai Beach by the Mineral Sands Corporation of Sri Lanka on installing the infrastructure for a mineral sands plant scheduled to come onstream by 1980.[17] The new complex will have an estimated production capacity of 500 tons of monazite per year.

United Kingdom.—Thorium Ltd., a subsidiary of Rio Tinto-Zinc Corp., Ltd., Widnes, England, reportedly stopped processing monazite as of November 1975.[18] Thorium Ltd. which was founded in 1914 to supply the United Kingdom with thorium nitrate for gas mantles, but soon expanded into production of rare-earth chemicals, planned to sell off its stocks and drop out of the rare-earth business.

TECHNOLOGY

An improved rare-earth solvent-extraction circuit was studied for upgrading the yttrium product from ion exchange barren solutions after uranium recovery. The results indicated that, by varying the flow ratios, pH, solvent concentration, and modifier, it was possible to raise the yttrium grade in the product from 30% to 60%. Possibilities were also indicated for group rare-earth separations.[19]

Refractory ceramics based on silicon nitrate powder with the addition of 10 to 20 weight-percent yttria, were under consideration as a high-temperature structural material for possible use in heat engines. These ceramics are resistant to high temperatures, oxidation, and corrosion. Thus they could allow an increase in the operational temperature of heat engines, which would produce fewer pollution-causing emissions and increase thermal efficiency.[20]

Research continued on the development of a rare-earth auto-emission-control catalyst that tolerates leaded gasoline. A typical formula for such a catalyst, which is also remarkably heat resistant, would be $(La_{0.6}Sr_{0.4})\ (Co_{0.9}Pb_{0.1})\ O_3$, where La could be another element from the lanthanum series. Another exhaust-control catalyst, which also works in the presence of leaded fuel, is being developed. Again, the catalyst was basically $LaCoO_3$, but does not contain noble metals.[21]

An oxygen-sensing device enabling automotive carburators to remain in optimum adjustment in relation to the air-fuel mixture was developed. The device, which uses a ceramic mixture of zirconium and yttrium oxides, generates a signal upon sensing the difference in oxygen content in exhaust and unburned air. This signal is fed into a miniprocessor that adjusts the carburetor.[22]

[21] Chemical Week. V. 117, No. 11, Sept. 10, 1975, pp. 39, 42.

In magnetohydrostatic (MHS) separation, nonmagnetic particles in a magnetic medium are stratified according to their densities. Very satisfactory results can be obtained when rare-earth salts of erbium, terbium, dysprosium, and holmium are used as the medium, because of the high magnetic susceptibilities of these salts. MHS separation would be best suited to free-flowing, coarse material of a low volume and high value, such as final stages of diamond recovery, jewelers' waste, and separation of nonferrous scrap.[23] This development would provide an application for rare-earth elements that are in low demand.

Work continued on rare-earth permanent magnets. By classifying and tabulating the properties of the rare-earth elements when alloyed with cobalt, new more powerful, high-temperature resistant magnets are expected. Also, these data will enable an engineer to choose exactly the magnetic device needed for a particular job. These powerful magnets could be used in monitoring the materials in a working jet engine or a hot nuclear reactor.[24] A rotor made with rare-earth-cobalt permanent magnets was installed in a new type of servomotor. The benefits included considerable savings in copper, iron, and in the magnet weight.[25]

A diffusion coating of 96% aluminum and 4% mischmetal showed an improvement over conventional aluminum coatings. The improvements were less spalling, added service life, and resistance to sulfidation and carburization. The new coating could be used on alloys specified for chemical-processing equipment and heat-treating furnaces.[26]

Rare-earth research continued at Bureau of Mines metallurgy research laboratories on a number of projects: Using rare-earth oxides as additives in high-temperature ceramics; producing mischmetal by sodium reduction of rare-earth chloride; determining optimum composition and conditions required to fabricate mischmetal-cobalt magnets; and testing the hydrogen-absorption capacity of various rare-earth-cobalt and rare-earth-nickel alloys for possible use in fuel-storage systems.

Single crystal fibers (50 micrometers or less in diameter) of neodymium-doped yttrium-aluminum garnet (Nd:YAG) were grown using a modified zone melting technique. The fibers had similar optical properties to larger rods of Nd:YAG. The combination of the fiber dimension and the low threshold of Nd:YAG gave this material a wide range of applications, particularly in optical communications.[27]

A new class of efficient, easily prepared, rare earth-doped vitroceramics for energy transfer from infrared to visible radiation were developed. They are composed of oxides of yttrium, lanthanum, gadolinium, or lutetium plus yttrium oxide and lead fluoride and an oxide of a typical glass-forming element. Experiments demonstrated that the concentration of the rare-earth ions was mainly in the microcrystalline phase, which accounted for the higher efficiency for conversion from infrared to visible radiation. These vitroceramics could possibly be employed as glass ceramic-laser material and in display applications.[28]

Single crystals of lanthanum hexaboride (LaB_6) were reported to be better than the tungsten cathode as an electron source in common electron microscopes and scanning electron microscopes. LaB_6 crystals had higher brightness and better stability even though they were tested under conditions developed for the tungsten cathode.[29]

Rhenium

By Larry J. Alverson [1]

Domestic rhenium mine production decreased 60% in 1975. However, consumption increased by over 33% and total stocks were drawn down to meet the increase. Prices for both metal powder and compounds continued to decline. Imports of metal powder increased slightly, while imports of ammonium perrhenate declined more than 70%. Bimetallic platinum-rhenium catalysts used in petroleum refining continued to be the major use for rhenium domestically and worldwide.

Table 1.—Salient rhenium statistics
(Pounds of contained rhenium)

	1971	1972	1973	1974	1975
Mine production [e]	7,250	6,100	7,000	[r] 5,000	2,000
Consumption [e]	7,600	4,800	4,400	4,500	6,000
Imports (metal and scrap)	377	168	1,437	40	59
Imports (ammonium perrhenate) [e]	3,435	1,921	3,040	3,287	966

[e] Estimate. [r] Revised.

DOMESTIC PRODUCTION

Rhenium production, as a byproduct of molybdenite (MoS_2) from various sources, decreased in 1975 to an estimated 2,000 pounds, contained in ammonium perrhenate. Closure of Kennecott Copper Corp's. rhenium recovery operation at Garfield, Utah, for most of 1975 was the principal reason for the decrease.

M & R Refractory Metals, Inc., at its Winslow, N.J., plant, produced rhenium salts for Utah International, Inc. (UI) from MoS_2 recovered at the Island Copper mine on Vancouver Island, British Columbia. Shattuck Chemical Co., Denver, Colo., recovered rhenium salts from Arizona byproduct MoS_2 concentrate. Molycorp, Inc. recovered rhenium salts from byproduct MoS_2 concentrate from Arizona porphyry copper ores.

The domestic industry operated at about 15% of production capacity in 1975, down from about 33% in 1974 due to excess producer, consumer, and dealer stocks.

Newmont Exploration Ltd., a subsidiary of Newmont Mining Corp., discontinued work on a process to recover rhenium from San Manuel molybdenite before the patented technique was fully developed. This action was due to both technical difficulties and unfavorable economics of the current rhenium market.[2]

CONSUMPTION AND USES

Estimated 1975 rhenium consumption was about 6,000 pounds, up more than 33% from that of 1974. Over 95% was used in bimetallic platinum-rhenium catalysts used principally in producing low-lead and leadfree high-octane gasoline.

---

[1] Industry economist, Division of Ferrous Metals.
[2] Newmont Mining Corp. Annual Report. 1975, p. 20.

The amount of domestic and worldwide catalytic reforming capacity accounted for by platinum-rhenium catalysts continued to grow. In 1975, for the first time, reforming units employing bimetallic catalysts accounted for more capacity than those using conventional platinum catalysts. Bimetallic capacity has increased about 14% per year for the past 4 years and should continue to do so in the near future. Platinum-rhenium's share of total bimetallic capacity stands at about 60% to 70%, or about 30% to 35% of total domestic reforming capacity.

Refineries such as Hunt Oil Co.'s Tuscaloosa, Ala., plant converted some reforming capacity from conventional to platinum-rhenium catalysts during 1975. Several new catalytic reforming units came onstream in 1975 employing platinum-rhenium catalysts. One such unit was at the Memphis, Tenn., refinery of Delta Refining Co., which employed the UOP R–16E catalyst. Unit capacity is 10,000 barrels per stream day, utilizing about 150 pounds of rhenium in 50,000 pounds of catalyst.

Platinum-rhenium catalysts are also used in producing BTX (benzene, toluene, and xylenes). One example is the Standard Oil Co. of California BTX unit at El Segundo, Calif. Other units exist but account for only a small percentage of total platinum-rhenium catalysts in use.

Chevron Research Co. developed a new bimetallic platinum-rhenium reforming catalyst named Type E. The catalyst contains 0.3 weight-percent each of platinum and rhenium on an alumina carrier. Together with new developments in operating procedures, the new catalyst reportedly results in better stability (lower catalyst fouling rate), better selectivity (which results in greater yields of aromatics and hydrogen and allows lower pressure operation), and lower catalyst cost. The catalyst and processing procedures are included in a new package called Rheniforming II, which allows a decrease in reformer pressure to 125 pounds per square inch (psi). It is especially attractive for the manufacture of BTX, since BTX manufacture is enhanced by low-pressure operation. When processing a predominantly paraffinic Arabian naphtha, reforming at 125 psi gave a 14% increase in total benzene-toluene yield over the 200-psi operation. A naphthenic California feedstock showed a 7% increase in benzene-toluene yield under similar conditions. Of the 50 Rheniformer plants now in operation or under construction, 23 are specifically designed for low-pressure operation.

Since the introduction of Rheniforming catalysts in 1967, none of the units Chevron has designed have required replacement of the catalyst due to process failure. The oldest catalyst produced 750 barrels of feed per pound of catalyst, was regenerated 12 times, and returned to the condition of a fresh catalyst after each regeneration. Total Rheniforming units now in operation contain about 10,000 pounds of rhenium in catalyst and have gone through over 100 regenerations.

Chevron has combined an improved catalytic hydrocracking and catalytic reforming process to upgrade lower valued heavy petroleum stocks into higher valued lower boiling products. While manufacture of motor gasoline is emphasized, the process combination gives the refiner flexibility to take advantage of the economic potential for production of jet fuel, middle distillates, and aromatics as markets develop. The reforming phase utilizes the Chevron Type D platinum-rhenium catalyst.

Joint developments by Atlantic Richfield Co. and Engelhard Minerals & Chemicals Corp. in the catalytic reforming area resulted in the Magnaformer process design and the E–500 and E–600 series platinum-rhenium catalysts. These catalysts have been well received as replacements in existing reforming units, and for use in new units designed for these more efficient catalysts. Currently over 60 units use the E–500 and E–600 series bimetallic catalysts. Engelhard estimates that the E–601 catalyst can perform efficiently over periods about 8 times as long as the conventional platinum catalyst. It can also be regenerated to essentially new condition. Of the commercial units operating with the E–501 catalyst, three or four have undergone as many as six in situ regenerations. With the E–601 catalyst, four regenerations have been completed, and the ensuing cycles are doing very well.

The remaining 5% of estimated domestic rhenium consumption was used in high-temperature thermocouples, X-ray tubes and targets, electrical contacts, electronic devices, vacuum tube and flashbulb filaments, heating elements, metallic coatings, electromagnets, and certain high-temperature alloys in research and development work.

Rhenium's commercial use in nickel-base high-temperature alloys is uncertain. It can be utilized effectively, but researchers appear to be designing around its use, probably owing to its high price and previously limited availability. However, the current price is less than half of what it was 4 years ago, when it peaked at well over $1,000 per pound, and stocks are high.

General Electric Co. (GE) is currently working under contract on nickel-based alloys containing 3 to 6 weight-percent rhenium for use in jet engine turbine blades. Completion of the development and evaluation program is planned for 1981. However, GE has been looking for ways to develop the alloys without the addition of rhenium.

Separate research continued on similar applications with up to 2 weight-percent and less rhenium additions to a nickel-based alloy.

PRICES

The price for rhenium metal powder during the year ranged from about $625 to $540 per pound, depending upon grade and quantity, decreasing toward $540 by yearend. The price for perrhenic acid, a starting material in certain catalytic applications, ranged from about $600 to $500 per pound, depending upon grade and quantity, trending toward $500 later in the year. However, large-quantity buyers were able to purchase metal powder and rhenium compounds at greater discounts.

FOREIGN TRADE

Imports for consumption of rhenium metal, waste, and scrap increased to 59 pounds from 40 pounds in 1974. Total value was $27,196. The imported rhenium was produced in the supplying countries from molybdenite obtained as a byproduct of porphyry copper ores mined in Canada, Chile, and Peru, and from sedimentary copper ores mined in Zaire, in which molybdenum is not a factor. The average value of imports was $464 per pound, representing the fourth consecutive year that value per pound of imports declined.

Imports of ammonium perrhenate (NH_4ReO_4), decreased sharply in 1975 to an estimated 966 pounds of contained rhenium valued at $442,000. All imports came from Sweden and West Germany. In addition, ammonium perrhenate, containing 837 pounds of rhenium valued at $344,692, was imported from Chile into bonded warehouses in 1975. All ammonium perrhenate material was imported under the basket classification "Ammonium compounds, not specifically provided for (TSUS 417.44)." A minor amount of wrought rhenium metal was imported from Austria in 1975.

The import duty on rhenium from countries with market economies remained at the January 1, 1972, rates of 5% ad valorem for unwrought rhenium metal, and 9% ad valorem for wrought rhenium metal. The duty on wrought and unwrought rhenium metal from countries with centrally controlled economies also remained unchanged at 45% and 25% ad valorem, respectively. The duty on imports of ammonium perrhenate from countries with market economies was 4% ad valorem; the duty on that from countries with centrally controlled economies was 25% ad valorem. The duty on rhenium waste and scrap was suspended indefinitely.

WORLD REVIEW

Canada.—The only source of Canadian rhenium production was from molybdenite concentrate associated with the porphyry copper ore from the Island Copper mine of UI on Vancouver Island, British Columbia. In 1975, shipments of molybdenite concentrate to the United States and Europe totaled about 1,750 tons and contained about 4,200 pounds of rhenium. The concentrate averaged 1,200 parts per million (ppm) of rhenium in MoS_2 and represented one of the highest concentrations of rhenium in the world. About 12,300 pounds of rhenium has been shipped from the mine since operations began in 1972; however, not all of the MoS_2 was treated for rhenium recovery. The recovered rhenium was toll-processed in Europe and the United States and returned to UI as ammonium perrhenate for subsequent sale.

Investigations of porphyry copper ore bodies in nearby areas have indicated similar concentrations of rhenium in MoS_2 associated with some of the deposits. Canadian rhenium reserves are estimated at 400,000 pounds, with the total resource estimated at 3 million pounds.

Chile.—The Chilean Mine Workers Federation offered to build a $7 million molybdenum-rhenium plant in northern Chile. The plant could process 10 million pounds of molybdenite per year and produce about $5 million worth of molybdenum oxide and rhenium annually. The Federation's 20,000 members offered to contribute 1 day's pay per month towards the project, up to $1.7 million, with the difference coming from foreign credits.

The expansion of the Chuquicamata copper operation, with expected trebling of molybdenum output and concomitant greatly increased rhenium capacity, was scheduled for completion in 1978. Feasibility studies for other potential copper-molybdenum operations with rhenium potential were continuing.

Chile exported rhenium to the United States in the form of ammoniun perrhenate; all of it went into bonded warehouses. However, these exports ceased as of June 1975.

Chilean rhenium reserves are estimated at 1.4 million pounds, with the total resource estimated at 4 million pounds. Chile remains one of the world's largest potential rhenium producers.

Germany, West.—Hermann C. Starck Company, Inc., at Goslar continued to produce rhenium from molybdenite concentrate imported primarily from Chile and Peru. Starck handled sales of its associates Gesellschaft für Elektrometallurgie mbH (which produces rhenium at Weisweiller, West Germany) and AB Ferrolegeringar (which produces rhenium at Trollhatten, Sweden). The combined production capacity for these operations is about 5,000 pounds per year.

Degussa, Inc., headquartered in Frankfurt, performed research on rhenium alloying applications and recovered rhenium from scrap material and MoS_2 concentrate.

Iran.—The Sar-Cheshmeh porphyry copper deposit in southern Iran was expected to produce 40,000 tons of ore per day in 1977. The predominant primary minerals are disseminated chalcopyrite, pyrite, and molybdenite; the ore body contains an estimated 450,000,000 tons of ore grading 1.13% copper sulfide and 0.03% molybdenite.[3] With an estimated content of 200 ppm rhenium in MoS_2 concentrate, the ore body could contain over 50,000 pounds of rhenium.

The National Iranian Oil Co. installed a 14,760-barrel-per-day reforming unit at its Teheran refinery during the year. The unit was designed by Universal Oil Products Co. (UOP) and goes under the trade name of a Unifining-Platforming combination unit. The unit employs one of UOP's bimetallic platinum-rhenium catalyst which supersedes the older platinum (monometallic) catalyst.

U.S.S.R.—Nonferrous production is oriented to the recovery of major metals, which reportedly results in the loss of a considerable amount of byproduct metals such as rhenium. The Balkhash copper complex in Kazakhstan recovers less than 50% of the rhenium in reverberatory gases and has a 15% overall recovery from the raw material. Soviet rhenium production averages over 2,000 pounds per year, most of which is consumed domestically. Total reserves are estimated at 800,000 pounds, with total resources estimated at 2.4 million pounds.

Zaire.—Although official statistics are unavailable, mine production of rhenium from Zaire averages about 200 pounds per year. The copper deposits from which the rhenium is recovered are of the sedimentary type, as opposed to the porphyry type from which about 98% of the world's rhenium is recovered. Rhenium is recovered from copper concentrate in Belgium but averages only about 10 to 30 ppm versus 200 to 1,500 ppm in MoS_2 concentrate associated with porphyry copper ores. Metallurgie Hoboken-Overpelt S.A., in Brussels, recovers the rhenium, and has capacity to produce several hundred pounds per year.

TECHNOLOGY

The Bureau of Mines published results of an investigation on the recovery and separation of molybdenum and rhenium from a process solution. The objective of the research was to develop a technique whereby reagents are recycled and high-purity products obtained. Emphasis was placed on the use of feed solutions derived by the electrooxidation of sulfide minerals. The researchers concluded that very high percentages of molybdenum and rhenium can be separated from a pregnant electrooxidation solution by a combined process utilizing solvent extraction, carbon adsorption, and crystallization. The final rhenium product, ammonium perrhenate, contained less than 80 ppm combined impurities.[4]

The Bureau of Mines completed construction and assembly of a commercial-size, 125-volt, 1,000-ampere, bipolar flow-through electrooxidation cell for recovering molybdenum and rhenium from various sulfide concentrates. The cell will be tested at the mill site of a major copper producer to determine its effectiveness for extracting molybdenum and rhenium from offgrade molybdenite concentrates. In-house tests were conducted with the cell on recovering molybdenum from electrooxidation solutions by calcium chloride precipitation. Molybdenum was recovered as calcium molybdate containing 0.02% to 0.15% sulfur. The rhenium was recovered from the solution after the calcium molybdate was removed by raising solution pH to 10 by addition of sodium hydroxide, and passing the solution through a bed of a strong anion exchange resin. Rhenium recovery by this procedure ranged from 70% to 80%.

[4] Fischer, D. D., D. J. Bauer, and R. E. Lindstrom. Recovery and Separation of Molybdenum and Rhenium From A Process Solution. BuMines RI 8088, 1975, 12 pp.

The Bureau of Mines also completed studies on chlorination of sulfide minerals and several prepared metal sulfides. The resulting data were analyzed with respect to kinetics of the reactions and application to nonpolluting methods of winning metals from sulfide ores. The researchers concluded that rhenium sulfides, depending upon their dispersion within the ore, may not react rapidly enough to be recovered; however, various complicating factors make it necessary to consider each source of ore separately when contemplating chlorination processing.[5]

The electronic properties of resistive films of rhenium and its alloys VR27–VP and MR47–VP, obtained by thermal deposition and cathodic sputtering, were studied. High temperature and prolonged use of resistors showed that films prepared by electron beam deposition and protected with a layer of SiO_2 had a negative temperature coefficient of resistance, and the relative change in the resistance after 500 hours at 400° C in air was not greater than 5% to 10%. Resistors prepared from the alloys had a somewhat lower temperature and time stability. Such resistors can be used as passive elements in microcircuits and radio devices that operate below 400° C.[6]

The development of alloys containing rhenium for electrical contacts was studied in an effort to increase the sensitivity, accuracy, and reliability of highly sensitive magnetoelectric relays and contact electronic measuring instruments. From an analysis of the requirements for the contacts, gold was selected as the base material, and rhenium gave the best alloy at less than 3% rhenium. These alloys reportedly proved better than existing alloys in their electrophysical and mechanical properties. The best gold-rhenium alloys, tested under industrial conditions, showed considerable promise.[7]

Electron-beam-melted molybdenum 47 weight-percent rhenium was strengthened by adding 0.08% to 0.10% carbon while preserving low-temperature ductility. Deformation strengthening of ternary alloys was observed during hot rolling. The recrystallization temperature increased with increasing carbon content. The alloy was also strengthened by adding zirconium carbide (ZrC). Low-temperature ductility was slightly decreased on adding 0.8% ZrC, but strength at 1,200° C was increased by a factor of two.[8]

Kennecott Copper Corp. received a patent on extracting rhenium from dilute industrial solutions. A solution (flue gas scrubbing solution, a raffinate, or dump leach liquor) is treated with iron or zinc powder to precipitate dissolved rhenium values, and also with copper or silver particles as a collector for the precipitated rhenium values. The fine precipitate is mechanically separated from the larger collector particles.[9]

A process was patented for recovering rhenium from molybdenite. Finely divided ore is contacted with an ammonium persulfate solution at 25° to 40° C so that a substantial portion of the molybdenum is dissolved along with copper and iron, whereas substantially all of the rhenium remains in the undissolved residue. The leach solution is separated and processed for molybdenum. The solids are leached to dissolve rhenium, and the rhenium is recovered by electrolysis.[10]

A patent was issued on extracting rhenium values from copper precipitates derived from solutions obtained by leaching rhenium-containing copper sulfide ore, or mine or mill wastes. The copper precipitate is slurried in a mineral acid at a temperature of less than 100° C, the slurry is injected with air and/or oxygen to selectively oxidize and dissolve the rhenium as the perrhenate ion, and the leach solution is separated and subjected to an ion exchange treatment or other conventional method.[11]

Salt

By Russell J. Foster[1]

Salt production in 1975 was 10% less than in 1974. This amounted to a total production decline of more than 4.7 million tons. The amounts of both brine and solar salt sold or used decreased 17%. There were smaller declines in the amounts of vacuum-pan, open-pan and rock salt sold or used. Prices of all forms of salt rose in 1975. Evaporated salt prices were up significantly, whereas rock salt and salt in brine exhibited only small price increases.

A depressed chemical industry was the primary cause of reduced salt consumption. The manufacture of chlorine-caustic soda, soda ash, and other chemicals required 4.91 million tons less salt as starting material in 1975 than in 1974. The lower chemical output was affected by environmental regulations as well as a generally lagging economy. Chlorinated solvents, pesticides, and chlorofluorocarbons were under attack for possible harmful effects on the environment, and their production was reduced accordingly. Two Solvay soda ash plants, which used salt as a raw material, were closed in 1975 because of restrictions on the objectionable effluent streams from the plants and because of higher energy costs.

DOMESTIC PRODUCTION

Total salt sold or used in 1975 was nearly 12% less than that of 1974. Declines were most notable in brine and solar salt. In 1975, there were 55 salt-producing companies operating 100 plants in 16 States and Puerto Rico. Twelve of these companies produced over 1 million tons each and thus accounted for 86% of the U.S. salt production. The five leading States in the amount of salt sold or used were as follows:

State	Percentage of total
Louisiana	29
Texas	21
New York	15
Ohio	12
Michigan	10
Total	87

Salt sold or used in 1975, by type, was as follows:

	Percent
Salt in brine	52
Mined rock salt	35
Vacuum-pan salt	8
Solar-evaporated salt	4
Grainer or open-pan salt	1

Directors of Diamond Crystal Salt Co. authorized a $2.5 million expansion and modernization program for its St. Clair, Mich., salt refinery that will increase granulated salt capacity 33% when it comes onstream in 1977. The company also planned to convert the plant back to a coal-fired boiler operation at a cost of $2.1 million.[2]

Morton Salt Co. announced a $2.8 million expansion program at its Manistee, Mich., plant to increase evaporated salt capacity 100,000 tons per year. Completion of the project was scheduled for early 1977.[3]

The water level in Utah's Great Salt Lake was expected to reach a 46-year high in 1975, making salt producers there adjust to processing a lake brine of reduced saline concentration. In addition, the high water level has forced the salt companies to heighten dikes around solar evaporating ponds.[4]

STOCKS

The total amount of salt held by producers at yearend was about 2.4 million tons, which represented 6% of 1975 production. Over 70% was in the form of rock salt and another 21% was solar salt. Solar salt had the highest percentage of its production in stocks, 32%. Rock-salt stocks were approximately 12% of the total production, while the amounts of open-pan and vacuum-pan salt production in stocks were 3.2% and 2.4%, respectively. Only a small inventory of salt in brine was on hand at yearend.

CONSUMPTION AND USES

The chlorine-caustic soda industry continued as the leading salt user in 1975, consuming 46% of the total. The amount of salt required for the production of soda ash was 11% of salt output, and the manufacture of other chemicals consumed another 2.5%. Therefore, of the salt sold or used in 1975, nearly 60% was utilized as raw material for chemicals, compared with almost 63% in 1974. The economy and environmental regulations both contributed to the significant decline in chemical production. Use of salt on highways declined slightly in 1975. However, there were localized shortages at yearend, particularly in Michigan.

Other categories in which salt consumption was down notably from 1974 included water-softener manufacturers and service companies, feed dealers, grocery stores, rubber production, and the textile and dyeing industry. Consumption of salt by most food processors was similar to that of 1974. Among those showing considerable gains in salt usage were feed mixers.

W Withheld to avoid disclosing individual company confidential data; included with "Other."

[1] Less than 1/2 unit.

[2] Includes shipments to overseas areas administered by the United States, Puerto Rico, exports, some shipments to unspecified destinations, and States indicated by symbol W.

[3] Data may not add to totals shown because of independent rounding.

[4] Differs from totals in tables 2, 4, and 5 because of changes in inventory.

[5] Differs from totals in tables 1 and 11-13 because of incomplete data on the distribution of imported salt.

PRICES

Salt prices quoted at yearend 1975 by Chemical Marketing Reporter, compared with yearend 1974, follow:[5]

	1974	1975
Salt, evaporated, common, 100-pound bags, carlots or trucklots, works	$1.43	$1.99
Salt, chemical-grade, same basis	1.54	2.23
Salt, rock, medium, coarse, same basis	.97	1.35
Salt, rock, extra coarse, same basis	1.02	1.40

The average value, per ton, of different classes of salt in bulk, f.o.b. works, as reported by the salt producers, was as follows:

	1974	1975
Evaporated:		
Open pans or grainers	$34.18	$43.02
Vacuum pans	34.56	43.01
Solar	9.30	12.01
Pressed blocks, all sources	36.77	41.42
Rock salt, bulk	7.14	7.34
Salt in brine	3.69	3.75

The weighted average price increase for all salt was 5%. Solar salt showed the greatest increase, 29%. The smallest rise in price occurred in brine at 1.6%. The higher prices in 1975 were due to the rising costs of labor, energy, and packaging materials. Toward yearend, two major producers, Diamond Crystal Salt Co. and Morton Salt Co., announced further price hikes of 8% to 12%.[6]

FOREIGN TRADE

In 1975, the United States imported 7.5% of its apparent consumption and exported 3.2% of its production. Canada continued to be the primary destination for U.S. salt exports, receiving nearly the entire quantity. The amount of salt exported to Canada nearly tripled in 1975. This, coupled with a 29% decrease in imports of Canadian salt, resulted in a favorable balance of trade in salt with Canada for the first time since 1955. The Bahamas replaced Canada as the principal source of imported salt with 35% of the total. An additional 32% of the salt imports came from Mexico, and 27% from Canada.

Table 9.—Salt shipped to the Commonwealth of Puerto Rico and overseas areas administered by the United States

Area	1974		1975	
	Quantity (short tons)	Value (thousands)	Quantity (short tons)	Value (thousands)
American Samoa	275	$16	210	$17
Puerto Rico	18,694	1,758	19,375	2,261
Virgin Islands	98	19	[1] 219	26

WORLD REVIEW

World salt production in 1975 was estimated at 179.1 million tons. Distribution of the salt production in 1975, by continent, was as follows:

	Million tons	Percent
Europe	62.9	35
North America	56.8	31
Asia	47.0	26
Oceania	5.5	3
South America	5.0	3
Africa	2.4	1

The 12 major salt-producing nations, which together accounted for 82% of the worlds salt are listed below:

	Percent of total
United States	23
People's Republic of China	18
U.S.S.R	8
Germany, West	5
United Kingdom	5
India	4
Mexico	4
France	3
Canada	3
Australia	3
Italy	3
Romania	2

Australia, Mexico, Japan.—The governments of Australia and Mexico, two countries which together supply 90% of Japan's salt needs, raised salt prices to bring them more in line with world rates. The situation was particularly delicate because most of the Australian and Mexican salt producers are partially owned by Japanese companies with ties to Japanese buyers.

Following some months of disagreement, Japanese industry accepted a 40% increase in the price of Mexican salt. At the height of the dispute, operations were suspended at Exportadora de Sal S.A., the salt mining concession of Japan's Mitsubishi Corp. This resulted in a halt to mining operations and exportation of salt until the new price agreement was reached. In a similar move, Western Australian salt producers demanded a 33.3% price hike. Although an interim increase of 24% was agreed upon at the beginning of 1976, discussions on further price increases continued. Finally, in March 1976, the Australian Government fixed the minimum price for salt exports at the originally demanded 33.3% higher level.[7]

Canada.—Salt production was down 12% compared with 1974 production. Strikes at four locations in Canada, which resulted in a loss of 67,000 man-days, contributed significantly to the decline in productivity.[8]

Israel.—In June 1975, the Governments of the United States and Israel signed a joint agreement to construct a prototype desalting plant on the Mediterranean coast. The initial module of the Israeli-developed system will be constructed and tested by 1978. The proposed expansion of the module into the full-size, 10-million-gallon-per-day plant was scheduled for 1980.

Morocco.—A rock salt mine in the Berrechid Basin, near the Atlantic port of Mohammedia, will be the basis for construction of a new chemical complex consisting of three plants. Salt will be used as a starting material for soda ash production in one of the plants, and chlorine-caustic soda production in another. Part of the chlorine will be used in the third facility to make polyvinyl chloride.[9]

Saudi Arabia.—Two Japanese firms reached agreement with the Middle East Economic Development Co. to set up a jointly-owned venture in Jidda to manufacture and install seawater-desalination facilities. Equipment-manufacturing operations could begin by mid-1977. Initially, the company will install five desalination plants, each with a daily capacity of 5 million gallons.[10]

e Estimate. p Preliminary. r Revised.

[1] Salt is produced in many other countries, but quantities are relatively insignificant or reliable data are not available.

[2] Less than ½ unit.

[3] Series revised to include byproduct output from potash works, not previously included.

[4] Includes an average annual production in the Canary Islands of about 13,000 short tons of marine salt.

[5] Year beginning March 21 of that stated.

[6] Excludes Victoria.

TECHNOLOGY

In 1973, the Atomic Energy Commission, now part of the Energy Research and Development Administration (ERDA), intended to bury the waste from atomic powerplants in a Kansas salt mine, but political and environmentalist opposition prompted a retreat from that position. Recently, ERDA abandoned the alternate plan to store the waste in tanks above ground, thus reviving the idea of burying it in deep salt caverns. As a result, ERDA was considering a deep salt mine in New Mexico as a possible waste burial site.[11]

Shell Oil Co. completed an expansion program that added two underground salt dome cavities at its Sorrento storage facility in southern Louisiana. These two new cavities plus two old ones are used to store hydrocarbons, and have a total capacity of approximately 3.5 million barrels.[12]

Test operations of a 3-million-gallon-per-day experimental desalting plant were begun at Fountain Valley, Calif., by the Office of Water Research and Technology, U.S. Department of the Interior, in partnership with the Orange County Water District. The best features of two commercial distillation processes, vertical-tube evaporation and multistage flash-distillation, have been combined into a single concept. Engineering studies indicate that the new system required less capital investment, provided improved operation, and produced lower cost product water than either of the two processes operating independently.

Great Lakes Paper Co., Ltd., Ontario, Canada, announced plans to implement a salt recovery process to eliminate salt pollution at a new pulp mill. The process reportedly can remove sodium chloride contamination from all sources by evaporating white liquor, at lower capital and operating costs relative to external effluent-treatment processes.[13]

A solar pond, in which the sun's radiation is trapped by a heavy salt deposit on the pond's bottom and a black plastic lining, was demonstrated in Columbus, Ohio. The heated water is prevented from rising to the surface and being cooled, as it would in regular ponds, by the dissolved salt. Collected heat is stored both in the heated water and the heated soil underneath. Fresh water circulating through coils of plastic hose at the pond's bottom furnishes heat to the desired location.[14]

Sand and Gravel

By Walter Pajalich[1]

In 1975, sand and gravel production, including industrial sand and gravel, decreased about 13% to 789 million short tons, valued at $1.4 billion. The value of sand and gravel used as construction aggregate decreased less than one-half percent in 1975.

About 97% of the sand and gravel produced was used as construction aggregate, and about 3% was used as industrial sand and gravel. Of the total construction aggregate, about 89% was produced by commercial operators and 11% by Government-operated pits with their own crews and equipment for use on publicly funded projects. Of the total construction aggregate, about 69% was used commercially and about 31% was used for publicly funded projects.

r Revised.

[1] Puerto Rico excluded from all sand and gravel statistics.

[2] Data for 1973-75 not directly comparable with those of years prior to 1973 because of increase in industry coverage (1973, 1974) and change in canvass form (1974).

[3] Value f.o.b. plant of processed sand and of processed gravel. Value in all other tables are f.o.b. plant of blended processed sand and gravel used as construction aggregate. Unit value of construction aggregate is generally higher than the unit value of unblended processed sand or gravel.

[4] Data may not add to totals shown because of independent rounding.

In 1974, Alaska sand and gravel production was reported as 117 million tons, of which a preliminary figure of about 100 million tons was reportedly used in the construction of the oil pipeline. The final sand and gravel production and consumption figure for the oil pipeline, as reported by the Bureau of Land Management for 1974, was 30 million tons, and about 13 million tons was produced by the remainder of the State's construction industry. Based on these new data, total U.S. sand and gravel production in 1974 was 905 million tons. In 1975, Alaska produced 48 million tons, of which about 41 million was consumed in the construction of the oil pipeline. Most of this was unprocessed sand and gravel sold by the Bureau of Land Management from Federal lands.

Of the 7,014 sand and gravel operations, 5,609 had processing plants associated with their land or dredging operations; 1,405 operations had no processing plant and the material was sold as mined. Some of the 5,609 operations have more than one plant on location for processing mined material from a single pit.

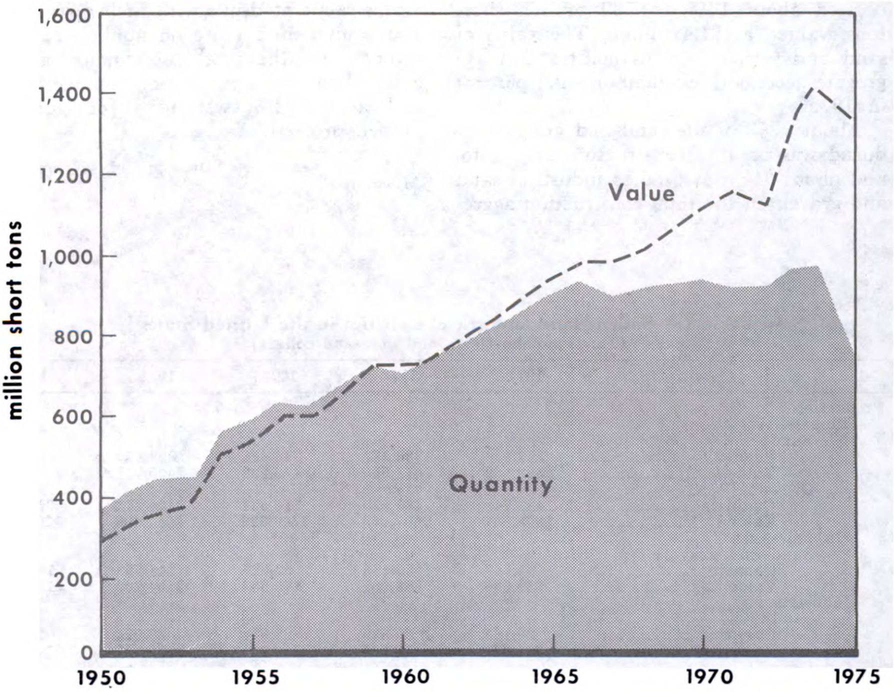

Figure 1.—Production and value of sand and gravel in the United States.

There were 5,871 construction sand and gravel operations with a production under 200,000 tons per year. These operations accounted for 42% of the total U.S. production. There were 689 operations with production between 200,000 and 500,000 tons; these accounted for 30% of the production. The remaining 239 operations, with production over 500,000 tons, accounted for 28% of the production.

There were 123 operations in the United States that produced only industrial sand and gravel and accounted for 23 million tons, or 83% of the U.S. industrial sand and gravel production. All of these had processing plants associated with the operation. Of these there were 111 operations with production of under 500,000 tons per year. There were 92 construction sand and gravel operations that produced some industrial sand and gravel. These accounted for 21 million tons of sand and gravel; of this, 4.5 million tons was industrial sand and gravel, or 17% of U.S. industrial sand and gravel production.

DOMESTIC PRODUCTION

In 1975, California with reported sales of 88 million tons of sand and gravel ranked first in the Nation. Alaska was second with production of 48 million tons. Michigan ranked third. Other States producing substantial quantities of sand and gravel, in descending order of production, were Illinois, Texas, Ohio, Minnesota, and Wisconsin. Combined, the eight leading States accounted for 362 million tons, about 46% of the total U.S. output. The value of the sand and gravel in these eight States was $592 million, 42% of the Nation's total.

The number of active commercial and noncommercial and industrial sand and gravel operations increased from 6,967 in 1974 to 7,014 in 1975. The active commercial and industrial sand and gravel operations were owned by 4,075 companies. The 679 active noncommercial operations were primarily worked by city, county, or State highway departments. An additional 834 operations reported that they were inactive during the year, and 920 operations were closed down. Sand and gravel operations opened up for use in the construction of the oil pipeline in Alaska are not included in these data.

Water and waste data in table 13 include construction and industrial sand and gravel operations. Reported amounts of water and waste generated depended upon the method of mining and type of operation. Deposits mined by dredges or below the water table and industrial sand and gravel operations generally reported higher amounts of processing water and generation of waste.

Sand and gravel information relative to the construction of the Alaska oil pipeline was left out of tables 9, 11, 12, and 13 because of uncertainty of data.

Wedron Silica Co., a division of Del Monte Properties Co., operated seven plants located at Emmett, Idaho, Cleburn, Tex., Sewanee, Tenn., Lugoff, S.C., Troy Grove, Ill., Wedron, Ill. and Byron, Calif. The operation at Byron, located about 26 miles from Stockton, is unique. The sand being mined from this deposit contains nearly the optimum amount of alumina (Al_2O_3) in the form of feldspar that is normally added by glass bottle manufacturers prior to melting and blowing. This natural composition of the sand makes it highly acceptable to the market after processing for removal of other deleterious minerals. Another prime factor is the manner in which the Byron plant processes the product, largely with specially designed or modified equipment. The operation displays considerable variance in plant layout and flow from conventional methods of washing, grading, and drying sand.

Like many other areas of the United States, Hawaii is having problems with its supply of good aggregates. This is particularly true on the island of Oahu, where most of the industry and population is located and most of the building is being done. Although there is an abundant supply of basaltic rock, there is very little natural sand available to blend with manufactured basalt sand to get the desired gradation. Digging beach sand on Oahu is illegal. Pacific Concrete & Rock Co., Ltd., of Honolulu was the first to develop coral limestone sand as a replacement for beach sand. The deposit is located at Waimanalo, 20 miles northeast of Honolulu on the island of Oahu. The deposit is a lithified oolitic limestone which includes a high percentage of sand. Following some drilling, blasting, and processing, the sand product is better in quality and more uniform in gradation than the beach sand.

In Louisiana gravel shortages have delayed construction and increased costs for current road projects totaling 1,700 miles. Until recently, gravel could be obtained close to most construction sites, but it is now being hauled increasingly longer distances at a cost of both time and money. Northwestern Louisiana projects are obtaining gravel from Arkansas, and centrally located projects are obtaining it from one of the few remaining large deposits in the State. The State Highway Director predicts the gravel will all be used up in a few years.

Contee Sand & Gravel Co., Inc., of Laurel, Md., has been sold to Boykin Resources, Inc., of Washington, D.C., for more than $30 million. Contee operates four sand and gravel plants, five ready-mix concrete plants, and a stone quarry.[2]

The North Dakota Multnomah County Planning Commission adopted and recommended to the county commissioners, which passed it, a mineral extraction ordinance which sets regulations for mining sand, gravel, rock, and earthen materials in the county. The ordinance provides that mining may be permitted in any district where the Planning Commission finds that an economic deposit of the resource can be shown to exist.

[2] Rock Products. V. 77, No. 5, May 1974, p. 138.

The Connecticut Department of Environmental Protection (DEP) has recognized the need to plan for sand and gravel mining land use. An article on "Planning for Sand and Gravel Mining," which appeared in the DEP Citizens' Bulletin, advocated sequential land use of sand and gravel mining sites, and protection of aggregate resources from preemptive land use until the aggregate materials can be recovered and utilized.

Pennsylvania Glass Sand Corp., a subsidiary of International Telephone and Telegraph Corp., opened a new automated glass sand plant 5 miles north of Mill Creek, Johnson County, Okla. The plant, with a capacity of 750,000 tons per year, will supply molding, Hydrafrac, and glass sand for new float glass manufacturing operations of Pennsylvania Glass Sand in Wichita Falls, Tex. The company has also begun the second phase of a $2.5 million expansion at its silica plant operation near Cayce, S.C.

Shipments are expected to begin soon from the new industrial sand plant of Georgia Marble Co. at Junction City near Columbus, Ga. The high-quality product will be marketed for a full range of industrial uses such as glass, filtration, blasting, and molding sand. Processing methods include preliminary washing and screening, desliming, attrition scrubbing, flotation, drying, and sizing. Glass sand will be shipped in bulk, and other grades will be available in bulk or bagged. The water used is impounded and recycled, with no release of water to the surface drainage.

The California Department of Transportation has planned to stop calling for bids on new highway construction for a year starting July 1, because it lacked the revenue needed to match Federal funds. Federal matching funds contribute over $400 million to the State's annual revenue.[3]

Construction Aggregates Corp.'s gravel plant on the Grand River, at Ferrysburg, Mich., one of the largest shippers of gravel has drastically curtailed production due to economic conditions. Normally 100 lake freighters are loaded per season; sand is shipped to customers such as the auto industry, and gravel products to the construction industry. As poor economic conditions continued, customers were served from existing stockpiles. Normal production of the processing plant is about 500 tons per hour. Each freighter is self-loading and takes 8 to 10 hours to load.[4]

The Sully-Miller Contracting Co. of Long Beach, Calif., purchased from The Flintkote Co. the assets of Flintkote's Western Concrete Materials Division located in southern California. Included in the sale are several ready-mixed concrete and aggregate operations in Los Angeles, Orange, San Bernardino and Riverside Counties.[5]

Fountain Sand & Gravel Co., of Bloomfield, N. Mex., acquired 180 acres of aggregate deposits south of Farmington, N. Mex.[6]

Oglebay Norton Co. acquired the silica sand operations in Texas and California of Chemical Express Co., Dallas, Tex., for $2.9 million. The operations acquired were the silica sand reserves and a processing plant near Brady, Tex. This operation is one of the main suppliers of fracture sand to the petroleum industry and the principal supplier to the company's grinding and processing plant near Riverside, Calif., which produces silica flour.

CONSUMPTION AND USES

In 1975, U.S. consumption of sand and gravel amounted to 789 million tons valued at $1.4 billion. The construction industry, the prime user of sand and gravel, consumed 97% of the tonnage, representing 89% of the value of the sand and gravel output in 1975. Of the sand and gravel consumed by the construction industry as concrete aggregate, 25% went into nonresidential and residential construction, 9% into highways and bridge construction, 7% into concrete products, and 2% into other uses. Bituminous paving consumed another 15%, roadbase and subbase 16%, fill 5%, and other consumption 2%. The remaining 19% was used as unprocessed sand and gravel; 9% as fill, 9% as roadbase and subbase, and 1% as other consumption.

PRICES

Representative carlot prices, f.o.b. point of delivery of sand in 19 cities at yearend 1975 ranged from $1.35 per ton in Detroit to $6.95 per ton in St. Louis, according to the Engineering News-Record.[7] The average of the sand prices reported was $4.15 per ton, compared with $3.05 per ton in 1974. Prices for either ¾- or 1½-inch gravel ranged from $1.90 per ton in Baltimore to $7.50 per ton in Kansas City. The average of the ¾-inch gravel prices reported for 19 cities was $4.61 per ton, compared with $3.55 per ton in 1974. For 1½-inch gravel, the average for 16 cities was $4.45 per ton, compared with $3.52 per ton in 1974.

Based on the Bureau of Mines canvass, the average value of processed sand and gravel sold or used as construction aggregate by producers, f.o.b. plant, was $1.88 per ton; value of unprocessed sand and gravel was $0.75, and value of industrial sand and gravel was $5.50 per ton. The overall average value of sand and gravel was $1.79 compared with $1.57 in 1974. Unit price of construction sand and gravel is based on the value of blended sand and gravel sold or used as construction aggregate. The estimated price for processed sand and gravel used for the Alaska pipeline ranged from $0.25 to $0.56 per ton versus $0.25 to $0.35 per ton for unprocessed. The quantity and value of Alaska sand and gravel production were included in determining the above national average prices.

FOREIGN TRADE

The United States exports gravel, construction sand and gravel, and industrial sand. Gravel exports in 1975 totaled 537,290 tons valued at $863,821; construction sand and gravel, 510,859 tons, valued at $1,111,410; and industrial sand, 2,171,109 tons valued at $13,071,346. Canada received 94% of the gravel, and Mexico 5%, and the remainder was shipped to 20 different countries. Canada received 95% of the construction sand and gravel and the Bahamas 4%, and the remainder was shipped to 14 different countries. Canada received 80% of industrial sand, Mexico received 15%, and the remainder was shipped to 63 other countries.

Of the 329,475 tons of crude sand and gravel imported in 1975, almost 100% was from Canada. Of the 44,887 tons of imported glass sand, 94% was from Australia, 4% from the Republic of South Africa, and the rest from six other countries.

WORLD REVIEW

West Germany.—The Kieler Institute in West Germany estimated a 4.6% annual growth rate for the foundry industry for the next decade. West Germany's high rate of growth between 1950 and 1968 was caused by the aftermath of World War II. Future rates will be more comparable with those of other industrial economies. As the rate of industrial growth slows, increased governmental investment may be anticipated to balance the situation. Output will come from fewer firms. Currently 8 to 12 tons of sand are needed for every ton of good castings produced. Because sand must be shaped by ramming, squeezing, or vibration and because of the high investment cost of the equipment involved, foundrymen will be looking for methods of mold production which increase capacity while reducing the length of the production cycle. The active elements in molding are likely to be increasingly chemical rather than mechanical. The trend is toward machines that will eliminate the need for binders and toward successful recycling of molding sands.[8]

United Kingdom.—A report by the Standing Conference on London and South East Regional Planning dealt with the development of additional rail depots in southeast England for the reception of aggregates. Aggregates from other parts of the country would ease the demand from existing operations in the region, and would reduce aggregate movements by road. The present rail movements within the South East Region are entirely sand and gravel, while imports from outside the region are predominantly crushed stone. In 1973, in Great Britain as a whole, the average distance rail haul was 104 miles for crushed stone and 44 miles for sand and gravel. Present rail movements of crushed stone in Great Britain account for 5.4% of total aggregate movement and sand and gravel account for 3.4%. By 1980 the British Quarrying and Slag Federation forecast that crushed stone movement by rail will be 1.9% and sand and gravel 8.3%.[9]

Harleyford Aggregates have replaced their riverside operation in Totnes, Devon, with a new plant. The new plant has an improved sand recovery system, lower power and water requirement, and more efficient use of manpower.[10]

Corey Sand & Ballast Co., Ltd., has commissioned the construction of a new washing and grading plant at Barling, Essex. The plant will replace an old one and is expected to produce 60 tons per hour of product. Total cost including site roads is about $400,000. Blending units will be incorporated in the plant and will operate from a panel in the control room.[11]

Tilling Construction Services, Ltd., finished construction of a large new facility for supplying aggregates to northeast England. This marine aggregate terminal at Howdon, Wallsend-on-Tyne, is centrally located with an excellent network of roads for marketing. It was built on a 3-acre site at a cost of about $1 million and can handle 500,000 tons per year. The terminal can accommodate the largest sand and gravel dredge in Europe. The vessel is over 350 feet long and incorporates its own cargo offloading facilities. It can discharge at a rate of 2,000 tons per hour using its own automatic grab gantry and conveyor system.[12]

TECHNOLOGY

Memphis Stone & Gravel Co.'s new Duke washing plant, located northwest of Arlington, Tenn., incorporates many innovative applications of automation. The plant, rated at 750 tons per hour of input capacity, can be operated by a crew of seven including the plant superintendent. The plant consists of two stages, a primary and finishing stage. Material flow through each stage is controlled by an automatic remote control system monitored by an operator from the centrally located master control tower. The master control console provides control of material flow for each stage independently. This independent control of either processing stage allows for complete stoppage during emergencies or repairs of one stage without disrupting production from the other stage. The primary stage, with a greater capacity than the finishing stage, provides material for the surge pile from which the finishing stage is fed. If there are delays, stoppages at the pit, or equipment repairs, the primary stage can be shut down while the finishing stage is supplied material from the surge pile, and the primary stage can feed the surge pile if the finishing stage is shut down.[13]

Transportation and handling costs are becoming a major concern to those companies that are forced to seek new sources of sand and gravel at considerable distance from their marketing area. As Western Paving and Construction Co.'s supply of sand and gravel near Denver became depleted, plans were made to develop 300 acres of land located 43 miles north of Denver that contain a 10- to 20-foot layer of sand and gravel. After considerable planning and comparing transportation advantages of truck versus train, the decision was made to use a unit train rail transport system. To supply 3,000 tons of sand and gravel to the company asphalt plants in Denver would have taken 30 trucks operating 9 hours per day, using 2,000 gallons of fuel. For about equal capital expenditure, 30 heavy-duty rapid-discharge rail cars can deliver the same amount of aggregate in 5 hours using only 400 gallons of fuel. Also, operating costs, maintenance, and personnel are lower for the unit train.

Each morning the 30-car unit train is picked up in Denver by 3 1,750-horsepower diesel locomotive with 4 crewmen including the engineer. The 43-mile trip takes about 2 hours. On arrival the cars are pulled directly beneath six silos. The engineer and conductor, communicating by radio with the silo operator, spot cars for loading. The return trip to Denver takes about 2½ hours. A complete unmanned automatic system is used to dump the cars quickly and cleanly as the ¼-mile train moves across a trestle at 1 mile per hour. In less than 15 minutes the entire train of 30 cars can be unloaded and the cargo ready for processing.[14]

The Minnesota State Department of Highways is using about 53,000 tons of taconite tailings in the improvement of State highways. The tailings are used as aggregate in the hot plant bituminous mix applied in resurfacing bridge decks and highways. Because of the gritty texture and the high quantity of silica, the tailings-bituminous mix is of particular value in restoring the skid-resistant surface of the roads. In contract road construction, the use of tailings is optional and depends upon whether the contractor can obtain a supply of tailings and if they can be shipped more economically than conventional aggregates.

Under an agreement with the Federal Highway Administration, the Ohio Department of Transportation will evaluate the Gussasphalt membrane placed as a protective surface on a concrete bridge deck. The object of this project and those in the past has been to demonstrate the practicality and cost effectiveness of mastic asphalt systems such as Gussasphalt in the United States. Gussasphalt is a German-originated mastic asphaltic compound, which has been successfully used on more than 1,500 miles of major highways in West Germany, and in other European locations, for more than 15 years. The higher cost of this material versus U.S. asphalt pavement reputedly is compensated for by longer life, low maintenance costs, and the ability to carry traffic as soon as it cools. It can be laid in subfreezing temperatures and is highly skid resistant. The compound embodies native lake asphalt, which holds colloidal material in suspension, a property not present in petroleum asphalt. The Gussasphalt used in Ohio consisted of 9.9% bitumen, 39.7% coarse aggregate, 29.7% fine aggregate, and 20.7% mineral filler. Filler can be any inert rock product finer than 200 mesh. The bitumen was a mixture of 80% AC 40 to 50 and 20% Trinidad Lake asphalt.[15]

Exacting specifications for aggregates have increased the need to beneficiate sand and gravel. The glacial sand and gravel deposits in the north-central United States contain chert, and many of the States in this area are specifying limits on the amount of chert in concrete aggregates. Garland Manufacturing Co. of Minnesota has developed a jig that separates lightweight chert from quality sand and gravel. The jig consists of a submerged screen box which has a forward-upward stroke of 3¼ inches and back again at about 70 stroke cycles per minute. The motion of the screen underwater causes the lightweight material to rise to the top of the bed, at the same time moving it towards the discharge end. Across the discharge end of the screen is a suction manifold similar to a vacuum cleaner, but using water in place of air. The suction is created by the water flowing out of the jig tank through the manifold and the suction tubes, which are also the chert discharge tubes. Using the Garland jig, F. Radant & Sons, Inc., of Manitowoc, Wis., in the operation of their 200-ton-per-hour sand and gravel operation, reduced the amount of chert from 4% to less than ½% in ¾-inch gravel.[16]

Scientists from the University of Southern California have been conducting studies of the sand and gravel deposits off the California coast. The first area of study is the land from Point Conception to Tijuana, Mexico, for the compilation of surface sedimentological data to determine where to start looking for major offshore sand and gravel deposits, and for profiling studies to determine the volume of minable sediments. This first phase of the studies started in September 1974 and ended in August 1975. The second phase, September 1975 to August 1976, will involve taking vibracore samples and will attempt to identify potential sites for mining sand and gravel. The third phase, September 1976 to August 1977 will involve determination of anticipated costs of mining, the best system of mining, and assessment of environmental impact and the development of guidelines for environmental reports.[17]

[14] Graham, F. M., Jr. Unit Train Solves Aggregate Supply Problem for Denver Firm. Pit & Quarry, v. 68, No. 5, November 1975, pp. 58–62.

[15] Road & Streets. Regular Spread Places Gussasphalt Bridge Deck. V. 118, No. 8, August 1975, pp. 27–28.

[16] Roads & Streets. Compact Washer Upgrades Gravel. V. 118, No. 12, December 1975, p. 33.

Conventional asphalt paving materials containing graded, good-quality aggregate have adequate strength for use on all types of roads. When substandard aggregates are used with asphalt alone, the resultant paving materials are not sufficiently strong for use on heavily traveled roads. However, when sulfur is added with these low-quality aggregates it increases the strength of the pavement up to or above that obtained with higher quality aggregates. In many areas high-quality aggregates suitable for road paving are scarce and must be transported from distant locations at considerable cost. Low-quality aggregates are often readily available locally. Under these conditions use of sulfur in paving materials can permit utilization of lower quality aggregates at considerable savings. Using this technology, typical paving materials consist of 13% to 15% sulfur, 6% asphalt, and 80% substandard sand and gravel. The primary participants in the sulfur-asphalt-sand pavement development program include Shell Canada Ltd., U.S. Bureau of Mines, U.S. Department of Transportation, Texas A & M Research Foundation, Texas State Department of Highways and Public Transportation, Louisiana Department of Highways, Barber-Green Co., and The Sulphur Institute.

For the past 10 years the Bureau of Mines has been actively involved in developing processes for recycling materials of value contained in incinerated and raw unburned urban refuse. The glass fraction from the Bureau incinerator residue pilot plant is a sandlike product of mixed color ranging in size from minus 20 to plus 150 mesh. The Bureau has developed methods for producing bricks, glass wool, floor tile, glass reflecting beads, and lightweight aggregate. Additional research at the University of Missouri was successful in utilizing rough glass concentrates from the Bureau's pilot plant in "glasphalt" paving material. The Bureau's process for reclaiming materials from raw refuse has been patented, and licensing is available to municipalities, industry, or individuals. The process, which involves shredding, magnetic separation, air classification, trommeling, jigging, and flotation, produces a concentrate essentially identical to that obtained from incinerator residue. The uses for this product are the same as those of incinerated residue. This technology is being installed on a commercial scale in Monroe County, N.Y., and Baltimore County, Md.

The Monsanto Research Corp., working under a Federal Highway Administration research contract, has developed a unique method for producing a waterproof concrete. Portland cement concrete is mixed with 3% by weight of 20- to 80-mesh montan and paraffin wax beads. After the concrete is placed and cured, it is heated to 185° F to melt the wax beads. A portion of the melted wax is taken up by the pores and capillaries in the concrete; upon cooling, it plugs these avenues against water or salt penetration, thereby producing a waterproof concrete. At its present stage of development, the process is considered ready for limited experimental application. The estimated material cost for concrete containing the wax is about double that of ordinary concrete. If two-course construction were used on a bridge deck and the wax were added only to the top 2-inch course, the added material costs would be about $2 per square yard of surface.[18]

Contractors realining a highway south of Los Angeles are mixing almost 200,000 cubic yards of rubbish with soil to construct embankments for the new route. Specifications by the California Department of Transportation, whose idea it was to use trash as fill, call for mixing the rubbish with soil in a one-to-one basis. Each layer of mix must be covered with solid soil. Although preparations were made to spray the area with odor-masking chemicals, only initial cuts produced any foul odors. When the rubbish is dumped, a bulldozer pulling a sheepsfoot roller spreads and mixes it. The site is expected to settle normally for several years. The base will be a combination of a 9-inch-thick layer of aggregate atop slightly more than 1 foot of aggregate subbase. The wearing surface will be about 5 inches of asphaltic concrete.[19]

[17] World Dredging & Marine Construction. Scientists Study Offshore Sand, Gravel Deposits. V. 11, No. 6, May 1975, p. 25.

[18] Federal Highway Administration, Offices of Research and Development. Newsletter. Issue 1, April 1975, pp. 1, 4.

One of the more unique sand and gravel operations with unusual mining techniques is in the Queen Mary Reservoir at Laleham near Staines, England. In the early 1920's, the reservoir embankments enclosed over 700 acres of gravel reserve. At present almost 450 acres of the reservoir are being excavated by floating dredges without impairing the operation of the reservoir by the Thames Water Authority. The project, which is operated by a consortium of local gravel companies under the name of Reservoir Aggregates, not only produces 600,000 tons of gravel per year but also will add 1,500 million gallons to the original 6,750-million-gallon reservoir capacity. Since the dredge operator cannot see the land where he digs, which is 40 feet under water, sounding devices record the depth of excavation. A laser beam enables accurate positioning of the dredges. Because of strong winds and high waves, 300-ton self-powered bottom dump barges have been built to match these conditions so that they can reliably carry the gravel to underwater stockpiles. A recovery dredge loads the gravel from these stockpiles onto a floating conveyor link to the processing plant.

A clam dredge was selected after tests had shown that other types of dredging equipment would raise the density of fine particles in suspension to a level greater than the Water Authority would permit. German dredging equipment manufactured by Mohr & Federhaff was chosen; a 5.5-cubic-yard bucket for the digging and a 7.8-cubic-meter bucket for the stockpile reclamation. All design and operations take into account the paramount need to protect the safety of the reservoir and the water it holds. Special provisions have been made for fueling the barges and dredges, and only certain lubricants are permitted. The Water Authority has power of approval or rejection over all machinery and materials brought into the reservoir and can even require blood tests of the employees.[20]

In the beneficiation of silica sand containing kaolin, and iron in carbonate form, crude silica sand is washed or deslimed in a centrifuge to remove kaolin. The centrifuge cyclone underflow is adjusted to a pH value of 8-10 and conditioned with a tall oil-fatty acid collector. The conditioned pulp is subjected to froth flotation to float off a portion of the iron carbonate. The underflow is treated with a cationic amine collector and subjected to a second froth flotation to float off the silica sand, leaving the iron carbonate in the cell underflow. The froth concentrate of silica may be leached with sulfuric acid to reduce its content of iron oxide to a very low percentage.[21]

Silicon

By Thomas S. Jones [1]

In contrast with 1974, the year 1975 was a difficult one for ferrosilicon and silicon metal producers. A decline in demand for silicon materials and consequent increasing availability became evident early in the year, leading to substantial worldwide reductions in production by the latter half of the year. Nevertheless, significant capacity expansions that either took place or were announced, both domestic and foreign, could lead to overcapacity by 1980, even with the return to normal levels of demand. Domestic price declines in response to weak demand were not great, because pressures from rising costs of electrical power and steel scrap were expected to continue.

Environmental concerns continued to be an important factor in plans for operating existing facilities or for designing new ones. In some foreign countries, these concerns apparently spurred producers to look outside their own country for expansion possibilities. Efforts continued at finding ways to dispose of silica dust from smelter emissions.

DOMESTIC PRODUCTION

Depressed economic conditions least affected production and shipments of 50% ferrosilicon, which, as indicated by data for the 25% to 55% ferrosilicon range, were almost as great as in 1974. Declines of one-quarter to one-half occurred for other ferrosilicon compositions and miscellaneous and specialty silicon materials. Production decreased 16% overall for silicon materials, exclusive of silicon metal, and shipments were off 22%. For silicon metal, production decreased 27% and shipments were 28% less. In Table 1, data for the 56% to 70%, 71% to 80%, and 80% to 95% ferrosilicon ranges are grouped, because only a small amount of ferrosilicon with 56% to 70% silicon was produced and ferrosilicon with 80% or more silicon content was not produced domestically. Data for silvery pig iron are withheld because there was only one producer.

Producer inventories increased for all silicon materials. In comparison with stock levels of recent years, ferrosilicon stocks increased from low to moderate levels, while those of silicon metal and specialty silicon materials went from moderate to high levels. Yearend stocks of silicon metal approximated a 2-month supply at 1974–75 rates of consumption.

Domestic production capacity for both ferrosilicon and silicon metal increased markedly. Between new facilities available for production in 1975 and those coming into production in 1976 or being engineered, scheduled capacity increases were over 200,000 annual tons for ferrosilicon (50% basis) and about 100,000 annual tons for silicon. Installation of environmental control equipment was an important part of this investment program. All primary silicon smelting continued to be by submerged arc furnace.

In ferrosilicon, the Metals Div. of Union Carbide Corp. had available throughout 1975 at Ashtabula, Ohio, a 60-megawatt (MW) computer-controlled furnace rated at 75,000 annual tons of 50% ferrosilicon. In December, Foote Mineral Co. completed the second phase of a modernization program begun in 1973 at its Graham, W. Va. plant by starting up a 24-MW furnace for production of ferrosilicon and proprietary silicon alloys. The new furnace replaced two remaining small furnaces at that plant. Planning continued on a similar furnace for the Keokuk, Iowa plant, but new construction other than for environmental control was not expected before 1977. Also at yearend, Ohio Ferro-Alloys Corp. energized a 46-megavolt-ampere (MVA) furnace at its Philo, Ohio plant, with full production expected shortly thereafter.

---

[1] Physical scientist, Division of Ferrous Metals.

A 24-MW furnace being installed at the Niagara Falls, N.Y. plant of the Airco Alloys Div. of Airco, Inc. will impact future ferrosilicon production. This furnace, expected to be operational by late 1976, will increase Airco's domestic ferrosilicon capacity by 30% to 43,000 annual tons, 50% basis. Power from a combination of nuclear and hydroelectric sources will be at the lowest cost of any Airco alloys facility. Additional future production is expected by mid-1977 from a new ferrosilicon facility at Bridgeport, Ala., a joint venture of International Minerals & Chemical Corp. (IMC) and Allegheny Ludlum Industries, Inc. The new facility will be adjacent to an existing plant of Tennessee Alloys Corp. (TAC), a division of IMC. TAC will operate the new facility, which will eventually replace present smelting furnaces at the Bridgeport plant, and result in a net 50% increase in output. The new furnace is to be a 40-MW unit furnished by the American Demag Corp., with a capability of 72,000 annual tons, 50% basis. Corresponding to its equity share in the joint venture, Allegheny-Ludlum will take 25% of production on a long-term basis for use in alloy steel production.

In silicon metal, Union Carbide's Metals Div. obtained its first full year of production at Alloy, W. Va. from a 30-MW furnace rated at 18,000 annual tons. During the year, the National Metallurgical Corp. division of Kawecki Berylco Industries, Inc. completed installation of a 25-MVA Demag furnace at its Springfield, Oreg. plant and began production of silicon metal. Capacity of that plant for high-purity silicon was raised by about 9,000 tons to about 14,000 tons per year.

Several new installations for silicon metal became operational near the end of 1975, all in Alabama. In December, a second 25-MVA Demag furnace was activated at the Selma (Alamet) plant of the Globe Metallurgical Div. of Interlake, Inc. This increased productive capacity by 12,000 annual tons and, coupled with other furnaces at the Beverly, Ohio plant, raised Interlake's annual silicon metal capacity to 46,000 tons. Likewise at yearend, the first of three furnaces, a 20-MW unit, was energized at the new silicon metal plant of Ohio Ferro-Alloys Corp. at Montgomery. The other two furnaces at this plant were scheduled to go into operation in the first half of 1976. At full operation, capacity of the Montgomery plant will be 36,000 annual tons of metal, making that of the company about 75,000 annual tons. At Sheffield, Reynolds Metals Co. activated a new 16.5-MW furnace in the fourth quarter. Completion of this second furnace raised annual capacity of that plant to about 18,000 tons. Silicon metal produced will mostly be consumed captively in production of aluminum casting alloys.

The aluminum industry is also expected to be the main consumer of silicon metal scheduled to be produced beginning in 1976 at the Addy, Wash. plant of Northwest Alloys, a subsidiary of the Aluminum Co. of America. Capacity for metal was rated at 16,000 annual tons. At this facility French-developed technology is to be used to manufacture as much as 24,000 tons of magnesium per year using ferrosilicon also produced within the plant.

Table 1.—Production, shipments, and stocks of silvery pig iron, ferrosilicon, and silicon metal in 1975

(Short tons, gross weight except as noted)

Alloy	Silicon content, percent		Producers' stocks as of Dec. 31, 1974 [r]	Production		Shipments	Producers' stocks as of Dec. 31, 1975
	Range	Typical		Quantity	Silicon content [1]

CONSUMPTION AND USES

Reported consumption of silicon materials declined generally, about one-fourth compared with 1974. A lesser decline was observed in the range including 50% ferrosilicon, while more pronounced decreases occurred for silvery pig iron, and especially for the 85% and 90% ferrosilicons. The largest demand in 1975 was for the 50% and 75% ferrosilicon grades, followed, on the basis of silicon content, by silicon metal, miscellaneous silicon alloys, and silvery pig iron. The decreasing order of end uses for silicon materials was cast iron, steel, nonferrous alloys, and silicones, with about 80% of consumption being accounted for by ferrous applications. Cast iron production consumed the greatest amounts of silvery pig iron, miscellaneous silicon alloys, and the 85% and 90% ferrosilicons, while steelmaking was the biggest user of 75% ferrosilicon. Iron foundries and steel plants together accounted for 98% of 50% ferrosilicon usage; 93% of silicon metal went into nonferrous alloys and silicones.

Decreases in consumption paralleled declines in major markets for silicon alloys and metal. Iron foundries and the steel industry each experienced production drops of about 20%. The aluminum industry, which uses silicon metal to make castings, suffered from an excess of supply over demand and reduced production. The cutback, 15% or more for domestic porducers, was partly caused by declines in the housing and transportation markets. Demand for silicon metal by the automotive and chemical industries rose in the latter part of 1975. For the first time since 1970, silicones suffered a decline overall, estimated at 5%, but a need was forseen for large increases in productive capacity by 1980. All three producers, Dow Corning Corp., General Electric Co., and Union Carbide Corp., were either already expanding productive facilities or planning to do so.

Efforts continued in developing specialty uses for silicon in high-temperature applications, in such forms as silicon nitride and silicon-silicon carbide composites, the latter prepared by infiltrating carbon filaments with liquid silicon.

Silicon metal produced by tonnage methods is used as raw material for the manufacture of the relatively small quantity of nearly pure silicon utilized for electronics and other specialized applications. The Bureau of Mines does not collect data on these specialty grades of silicon, which have a high unit value.

Consumer stocks of silicon material declined substantially from those at the end of 1974 for all but the 56% to 70% ferrosilicon range. Stocks for this range, the 71% to 80% range, and for silicon metal dropped to moderate levels, while those of other silicon materials decreased to recession levels, especially for the 81% to 95% range.

PRICES

Prices of silicon materials, as quoted in Metals Week, followed the pattern observed in several other metals industries during the recession year of 1975. Because of large inventory accumulations of both domestic and imported material, prices declined throughout the year. However, U.S. producers effectively maintained prices and reduced production rather than engaging in price cutting in a weak market. Imported material, which had been selling at highly inflated prices in 1974, therefore showed the greatest price declines. Prices for imported material began the year substantially above those for domestic material, but fell rapidly close to or below domestic prices for most of the year. In March 1975, Foote Mineral Co. began giving a 6% rebate on silvery pig iron because of lower scrap iron costs.

Ferrosilicon, which is priced on the basis of silicon contained, declined only slightly in price for domestic product. The decline took place in the spring, and amounted to 3% and 5% for 50% and 75% ferrosilicon, respectively. Per pound of silicon contained, the 50% grade decreased from 33.5 to 32.5 cents and the 75% grade dropped from 38.5 to 36.5 cents. The c.i.f. price of imported 75% ferrosilicon decreased several times, declining 50% overall on the basis of the middle of the range for high and low quotes, from 55 to 70 cents to 28 to 34 cents.

Prices for domestic silicon metal, on the basis of the midrange, were lowered 13% through the year for both the 0.35% and 1% maximum iron grades; the former from 46.5 to 59.9 cents to 46.4 cents per pound and the latter from 42.25 to 55 cents to 42.25 cents per pound. Also on the basis of the midrange, imported silicon metal (c.i.f. price, grade not specified) decreased 33%, from 55 to 75 cents to 42.5 to 44.5 cents per pound.

FOREIGN TRADE

Exports of ferrosilicon were the highest in terms of value ever, and second in quantity only to those in 1970. The largest amounts were exported to Canada and Sweden, 21,498 and 9,164 tons, respectively, which together accounted for about 80% of both total quantity and value. Exports, which included silicomanganese, went to 22 countries. Data specific to exports of silicon metal were not available.

Compared with 1974, imports dropped 51% in volume and 37% in value for ferrosilicon overall, and 35% in volume and 61% in value for silicon metal. Imports in relation to U.S. production and reported consumption were at a significant level for 75% ferrosilicon and for ferrosilicon containing 80% or more silicon. Imports of 75% ferrosilicon were the most significant on a volume basis, amounting to about two-fifths of reported consumption and of domestic production.

The 75% grade of ferrosilicon accounted for more than three-fourths of ferrosilicon imports. Norway shipped about one-half the total 60% to 80% silicon range while Canada, Japan, and Sweden, each with about one-tenth of the total, were the next largest sources. Imports in this range from Sweden, France, and Yugoslavia declined notably compared with 1974. The next largest import class was that for 8% to 60% silicon, which comprised more than one-fifth of ferrosilicon imports. The three main sources within that class were Japan and France for 50% ferrosilicon, and Canada for ferrosilicons averaging about 30% silicon. Average silicon content of all imported ferrosilicon rose again to 67%. The Republic of South Africa and Norway were the dominant identifiable sources of commercial-purity silicon metal, as South Africa, in its first year as a metal producer, shipped the most to the United States.

The marked increase in exports and decline in imports did not change the U.S. position as a net importer of ferrosilicon. Net imports amounted to almost 32 million tons and a trade deficit of about $27 million.

Table 5.—U.S. exports of ferrosilicon

Year	Quantity (short tons)	Value (thousands)
1973	15,984	$4,051
1974	6,575	3,338

WORLD REVIEW

Expansions of ferrosilicon and silicon metal production facilities either carried out or projected for the near future were at least comparable in total with those in the United States. In some countries, expansion appeared to be forestalled by concern about effects on the environment of the smelting facilities or the powerplants required to furnish additional electrical energy.

Australia.—A new 45-MVA ferrosilicon furnace will allow Broken Hill Proprietary Co. Ltd. (BHP) to produce rather than import its ferrosilicon needs. The furnace, of Norwegian design, was part of an expansion at the Bell Bay, Tasmania, plant of the Tasmanian Electrometallurgical Co. Pty. Ltd. (TEMCO), a BHP subsidiary. The plant, whose ferromanganese and silicomanganese production also increased, will be fed an additional 50,000 annual tons of local Tasmanian quartzite. About half of the increase in ferrosilicon manufacture will be available for export.

Other plans for new ferrosilicon production in excess of 50,000 annual tons at Electrona, Tasmania, were dropped, partly because of inflated costs. A plant was planned to be built in place of an existing carbide facility. Consolidated Gold Fields Australia Ltd. was a leading member of a consortium formed for the project, which at one point had attracted Norwegian interests.

Canada.—Late in the year Chromasco Ltd. began operation at Beauharnois, Quebec of a new ferrosilicon furnace of its own design and manufacture. The furnace, mainly for 50% ferrosilicon, is a 24-megawatt unit with a production capacity of about 30,000 annual tons.

Construction began in June at Becancour, Quebec on a ferrosilicon and silicon metal plant by SKW Electro-Metallurgy Canada Ltd. (SKW-Canada). The plant was scheduled to begin producing in the first part of 1976 about 60,000 annual tons to be divided about equally between ferrosilicon and metal. The plant will take advantage of hydropower and deep sea port facilities, and annually consume 130,000 tons of quartz. SKW-Canada is 85% owned by Suddeutsche Kalkstickstoff-Werke AG, Trostberg, West Germany, and 15% by A/S Ila og Lilleby Smelteverker, Trondheim, Norway, both ferroalloy producers.

Iceland.—Icelandic Alloys Ltd., a joint undertaking between the Government of Iceland and Union Carbide Corp., began building a plant on the southwest coast for production of about 50,000 annual tons of 75% ferrosilicon. The company was established on April 28, 1975, following parliamentary approval and more than 3 years of preparatory work. Financing of a total capital investment of about $70 million was to be 55% by the Government and 45% by Union Carbide. This is one of several projects envisioned by the Government to utilize hydroelectric resources under development. The company was to operate under terms similar to those accorded other comparable export industries. Union Carbide was to market the product mainly for sale to Europe.

Construction was originally scheduled for completion in 1977–78. The plant is located at Grundartangi on Hvalfjordhur, a short distance north of Reykjavik, at a latitude roughly that of Trondheim, Norway. The plant was expected to use about one-third the output of the 150-MW Sigalda hydroelectric project, a new State-owned power station being built.

Japan.—Japanese producers began the year seeking methods of assuring supplies of silicon materials at reasonable prices in the face of domestic productive capability about equal to demand. Contracting on a long-term basis between producer and consumer cartels was judged an effective way of stabilizing supplies and prices. However, as the year progressed, steel production and silicon requirements declined sharply. Ferrosilicon and silicon metal producers were forced to sell in the home market below cost, while reducing production to half or less of capacity. The revised estimate for ferrosilicon production in fiscal 1975 was 338,000 tons. Nevertheless, late in the year Ube Denki Kagaku began operating a 40-MVA ferrosilicon furnace rated at 33,000 annual tons at Ube.

Korea, South.—A 28-MVA ferrosilicon furnace was started up in midyear by the Inchon Ferro-Alloy Co., a joint venture between the State steel company (Inchon Iron & Steel Co., Ltd.) and Japanese firms (Joetsu Denro Kogyo and Mitsui & Co., Ltd.). Building of the plant began in the latter part of 1974, production from which is expected to exceed 10,000 annual tons.

Philippines.—Electro Alloys Corp., the first overseas manufacturing project of Japanese ferrosilicon producers, moved ahead towards beginning production in 1976. In midyear construction began on Mindanao of a ferrosilicon furnace rated at 13,700 annual tons. The Philippine Laurel Co. owns 60% of Electro Alloys, while the balance of ownership is equally divided by the Japanese firms, Nippon Denko Co., Ltd. and C. Itoh & Co., Ltd. Output is expected to go mainly to Japan. Maria Cristina Chemical Industries (MCCI) began ferrosilicon production from a 21-MVA unit on Mindanao in the latter half of 1975. MCCI also financed 60% of a new company (Mindanao Alloy Corp.) to produce ferrosilicon. Japanese interests provided the rest of the investment. Installation of two 25-MVA furnaces was projected to give a production capacity of 30,000 annual tons by late 1977.

South Africa, Republic of.—Silicon Smelters (Pty.) Ltd. brought all three 25-MVA silicon metal furnaces into operation at its $30 million plant near Pietersburg, about 150 miles northeast of Pretoria. These Elkem units have already produced above the nominal capacity of 33,000 annual tons, although not yet on a sustained basis. Output from this plant is able to meet all present and foreseeable South African silicon metal requirements. Presently about 95% of the output is to be exported, one of the largest customers being the Aluminum Co. of Canada, Ltd. (Alcan), one of the three owners of Silicon Smelters.

U.S.S.R.—Western technical and financial assistance, including that of U.S. ferroalloy producers, was sought for a 60,000-annual-ton silicon metal plant to be located in Siberia. Negotiations have been underway since the latter part of 1974 for this and other ferroalloy and aluminum plants projected to be completed in 1980. Products of the new plants are likely to be consumed within the U.S.S.R. and neighboring Eastern bloc countries.

Venezuela.—Two projects, which between them would ultimately lead to annual production of 100,000 tons of ferrosilicon, fell behind or were delayed beyond the original timetable. Production from the first of three units of a joint project between the Government and Sumitomo Shoji Kaisha (Japan) was anticipated in 1976, with projections of final capacity of 50,000 annual tons in 1978. A 1-year delay developed for the Venbozel joint venture, and plans for attaining a production level also of about 50,000 annual tons were moved back to 1978. The Venbozel project, begun as a joint effort between the French company Nobel Bozel S.A. and the Venezuelan Corp. of Guyana (CVG), attracted Japanese interests for participation in constructing a third furnace. Scheduled production from the first furnace at Mantanzas was delayed until 1977.

Silver

By Harold J. Drake [1]

Domestic mine production of silver in 1975 totaled 34.9 million troy ounces compared with 33.8 million troy ounces in 1974. The increase was accounted for mainly in metal from silver ore mining operations. Mine production of silver in Idaho rose 12%, while that in Arizona fell 1%. These two States accounted for 58% of the total output in 1975. Other States reporting increased production included Colorado, 21%; Missouri, 6%, and Nevada, 84%. Declines were reported for Michigan 2%, Montana 25%, New Mexico 34%, and Utah 12%.

Production of marketable silver at refineries, which used foreign and domestic concentrates and ores and scrap feed material, totaled 109.7 million troy ounces compared with 119.4 million troy ounces in 1974. A 4-million troy ounce decline in silver production from imported concentrates and ores and a 9-million troy ounce decline in silver output from coins was not offset by increases in refinery output from other materials. Silver from scrap produced and recycled at refineries totaled 50.5 million ounces, a level only slightly higher than that of 1974.

Consumption of silver declined 9% to 160.4 million troy ounces. Industrial use was off 10% whereas coinage use nearly tripled.

On January 2, 1975, the average price was 427.0 cents per ounce, and on December 31, 1975, the average price was 416.5 cents per ounce. The year high of 522.5 cents per ounce was reached on August 7, and the year low of 391.0 cents per ounce on December 15. The average price in 1975 was 441.8 cents per ounce compared with 470.8 cents per ounce in 1974.

U.S. imports of silver totaled 90.4 million ounces, a level well below the 133.4 million ounces imported in 1974. Exports, in contrast, rose 77% to 32.6 million ounces.

Industry stocks at yearend totaled 34.6 million ounces, a decrease of 14.7 million ounces from 1974. Treasury bullion stocks in the Bureau of the Mint were reduced by 3.0 million ounces to 41.0 million ounces. Department of Defense stocks available to defense contractors were 8 million ounces. The total amount of silver in the national stockpile remained at 139.5 million ounces with 117.8 million ounces available for disposal. Congressional approval is required for disposal of silver from the national stockpile and in 1975 it was not given.

Trading volume on the New York Commodity Exchange (COMEX) increased 36% over 1974. The Chicago Board of Trade (CBOT) trading volume increased 34% over 1974. COMEX warehouse stocks increased 26% in 1975, while CBOT stocks nearly doubled.

World mine production of silver totaled 294.3 million ounces compared with 294.9 million ounces in 1974.

Legislation and Government Programs.—Silver remained eligible for exploration assistance of up to 75% of approved costs under a program conducted by the Office of Minerals Exploration, U.S. Geological Survey. No loans were made in 1975.

DOMESTIC PRODUCTION

Domestic mine production of recoverable silver increased slightly to 34.9 million ounces. This level of production provided 22% of U.S. demand in 1975. Idaho accounted for 40% of the output, Arizona 18%, and Colorado 10%. Missouri, Montana, Nevada, and Utah, in the aggregate, accounted for 27%, and 14 other States accounted for the remainder. About 35% of the silver came from copper mining operations, 33% from silver ore, 15% from lead ore, and 14% from copper-lead-zinc ores. The remainder came from ores of gold, gold-silver, or zinc, and from old tailings.

Refinery production of marketable silver totaled 109.7 million ounces, 55% of which came from concentrates and ores, both foreign and domestic, with the remainder coming from old scrap. Recovery from domestic ores and concentrates rose about 2%, whereas recovery from imported ores and concentrates, continuing a decline begun in 1973, dropped 13%. Production of silver from coins retreated sharply from the very high levels of 1974 and was the reason for a 12% drop to 49.6 million ounces of silver extracted from old scrap. Production from new scrap, 50.5 million ounces, was only slightly above that of 1974.

The 25 leading silver producers (table 3) accounted for 81% of domestic production. Four of the leading producers mined silver ores, while most of the remainder mined copper, lead, and zinc ores. Nine of the leading mines produced in excess of 1 million ounces each during the year.

Hecla Mining Co., Wallace, Idaho, reported production of 4.2 million ounces of silver in metallic concentrates in 1975.[2] Hecla's Lucky Friday mine accounted for three-fifths of this output, and the company's share of the Sunshine Unit area for one-third. Hecla's share of the Star-Morning Unit area accounted for the remainder. The Lucky Friday mine produced 2.54

---

[2] Hecla Mining Co. 1975 Annual Report. 28 pp.

million ounces of silver from 173,245 tons of ore averaging 14.67 ounces of silver per ton. Both tonnage and grade were higher in 1975 than in 1974. Hecla's share of the Sunshine Unit area totaled 1.44 million ounces from 62,034 tons of ore averaging 23.14 ounces of silver per ton. A tonnage increase in 1975 was accompanied by about a one-half ounce decline in grade.

Production of silver from the Galena mine by ASARCO Incorporated totaled 3.35 million ounces, a slight decline from that of 1974.[3] ASARCO reported the completion of its new Coeur silver mine in Idaho with a capacity to produce concentrates containing 2.2 million ounces of silver per year. Production was scheduled for 1976. Construction of the Ontario mine, Park City, Utah, was completed. The mine, in which ASARCO has a 40% interest, has the capacity to produce 1.2 million ounces of silver per year.

Production of silver by The Bunker Hill Co., a subsidiary of Gulf Resources & Chemical Corp., rose 3% to 6.98 million ounces.[4] Most of the company's silver production came from the Bunker Hill mine which ranked as the eighth largest producer in 1975, and the Crescent mine which ranked as the eleventh largest silver producing mine.

The Anaconda Company reported that production of byproduct silver at its Berkeley pit in Montana totaled 2.35 million ounces, down sharply from the 3.57 million ounces produced in 1974.[5] Adverse economic conditions continued in 1975, and resulted in sharply curtailed copper mining by Anaconda which, in turn, led to curtailed silver production. The Berkeley pit was the fourth largest silver producer in 1975.

Production at the Sunshine mine totaled 5.13 million ounces, an increase of 1.28 million ounces over that of 1974. The Sunshine Mining Co. operated the mine and distributed part of the output to Hecla Mining Co. The Sunshine mine was the largest silver producer in 1975.

A new silver scrap plant with a daily productive capacity of 40,000 ounces of silver was completed.[6] Using a hydrometallurgical extraction process, the plant will produce silver that meets anode, nitrate, and photographic standards.

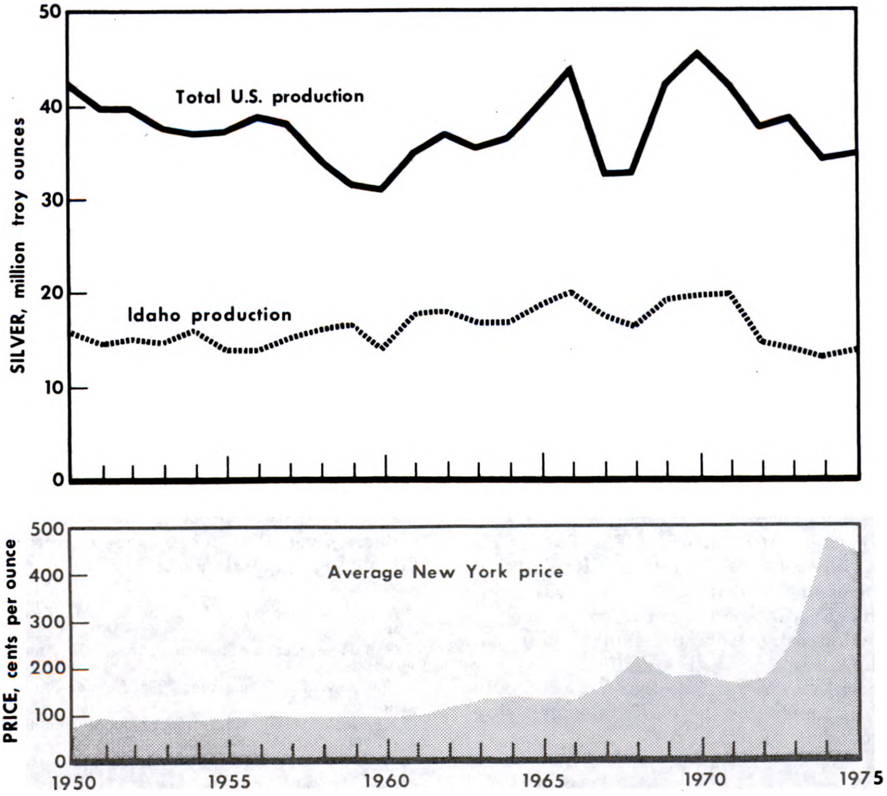

Figure 1.—Silver production in the United States and Idaho and price per ounce.

CONSUMPTION AND USES

Consumption of silver in 1975 declined 9% to 160.4 million ounces reflecting the generally poor economic conditions in the United States during most of the year. Contributing to the decline in consumption were high silver prices, more internal recycling, and substitution of lower cost materials for silver.

Consumption of silver in photographic materials, the largest use category, declined 7% to 46.1 million ounces. The photographic industry increased the use of nonsilver photographic processes, and also increased the recycling of silver. Use of silver in contacts and conductors in electrical and electronic products declined 13% to 27.2 million ounces. Consumption in coins, medallions, and commemorative objects in 1975, 7.2 million ounces, was one-third of that reported in 1974.

Compared with 1974, consumption in electroplated ware declined 4.5 million ounces (34%), dental and medical supplies 0.9 million ounces (37%), brazing alloys and solders 0.9 million ounces (6%), and mirrors 0.8 million ounces (20%).

The most significant use category, in terms of quantity, reporting an increase in consumption was jewelry which used 7.6 million ounces more in 1975 than in 1974. Jewelry use in 1975 totaled 12.7 million ounces. Use in sterling ware was up 1.6 million ounces to 23.7 million ounces. Use of silver in catalysts rose 1.5 million ounces to 8.8 million ounces. Minor uses reporting increased consumption were batteries and bearings. Silver use in coinage, which accounted for 2% of total consumption in 1975, rose to 2.7 million ounces, compared with 1.0 million ounces in 1974.

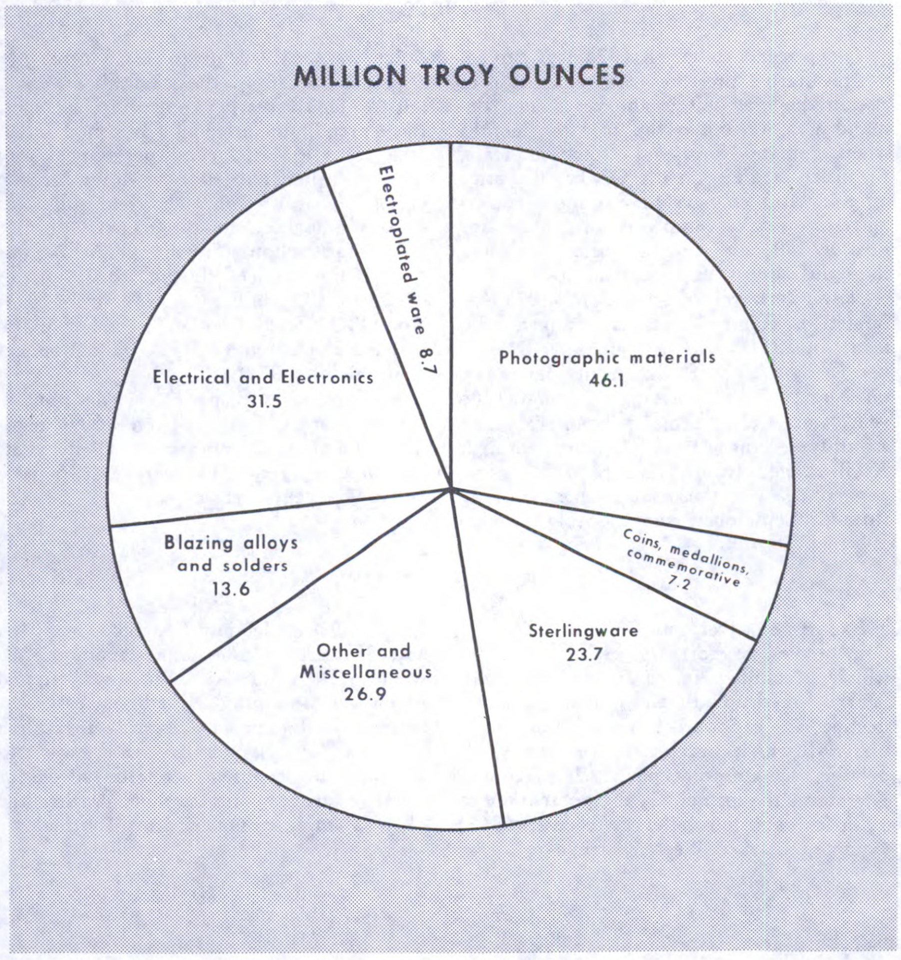

Figure 2.—Silver consumption in the United States, 1975.

STOCKS

Total yearend stocks of silver were, exclusive of the strategic stockpile, 207.8 million ounces compared with 186.7 million ounces at yearend 1974. By yearend 1975, industry stocks had been reduced 14.7 million ounces to 34.6 million ounces. Another 3 million ounces were disposed of as Treasury bullion stocks were reduced to 41.0 million ounces consisting of bullion, coin bars, and coinage metal fund silver. Stocks in registered vaults of COMEX rose by 17.9 million ounces to 85.7 million ounces, whereas stocks in vaults of the CBOT nearly doubled to 38.5 million ounces. Department of Defense stocks at 8 million ounces were a third higher than at yearend 1974. No action was taken by Congress to authorize disposal of the 117.8 million ounce excess portion of the 139.5 million ounces held in the strategic stockpile.

PRICES

The price of silver in 1975 was subject to speculative pressures that caused it to rise in the first half of the year when demand was weak and fall in later months when demand improved. Inflation fears, the price of grain on the CBOT, the price of gold, and changes in the international currency market appeared to have far greater influence on the price of silver than did supply and demand.

New York silver prices in 1975, as quoted by Handy & Harman, ranged from a low of 391.0 cents per ounce on December 15 to a high of 522.5 cents per ounce on August 7. The average price for the year was 441.8 cents per ounce. The monthly average from January through April ranged from 419.2 to 435.7 cents per ounce. For the next 5 months, May through September, the monthly average range was 448.9 cents to 492.5 cents per ounce. Thereafter, the monthly average fell to 408.5 cents per ounce in December. By yearend, the price of silver had fallen 10.5 cents to 416.5 cents per ounce from that prevailing at the beginning of the year. The fall from the year high in August amounted to 106.0 cents.

Trading volume on the COMEX was 14.5 billion ounces during 1975, an increase of 3.9 billion ounces over 1974. The CBOT trading volume was 9.8 billion ounces, an increase of 2.5 billion ounces over that in 1974.

Average monthly prices on the London Silver Market ranged from 409.0 cents per ounce in December to 493.5 cents per ounce in July. The average 1975 price was 444.2 cents per ounce.

FOREIGN TRADE

Exports of silver rose 77% to 32.6 million ounces. Exports of refined bullion, which accounted for 69% of the total, nearly quadrupled and offset a 21% decline in exports of waste and scrap material which accounted for nearly all of the remaining exports. The United Kingdom, the principal foreign market in 1975 for exported material, received 59%; Canada, 10%; West Germany, 10%; Japan, 9%; Belgium-Luxembourg, 5%; and Switzerland 4%. The remaining 3% went to 10 countries. Bullion was shipped mainly to the United Kingdom, West Germany, and Japan. The decrease in bullion imported by Canada in 1975 was attributed to declining need for silver for use in sterling coins commemorating the 1976 Olympic games held in Montreal.

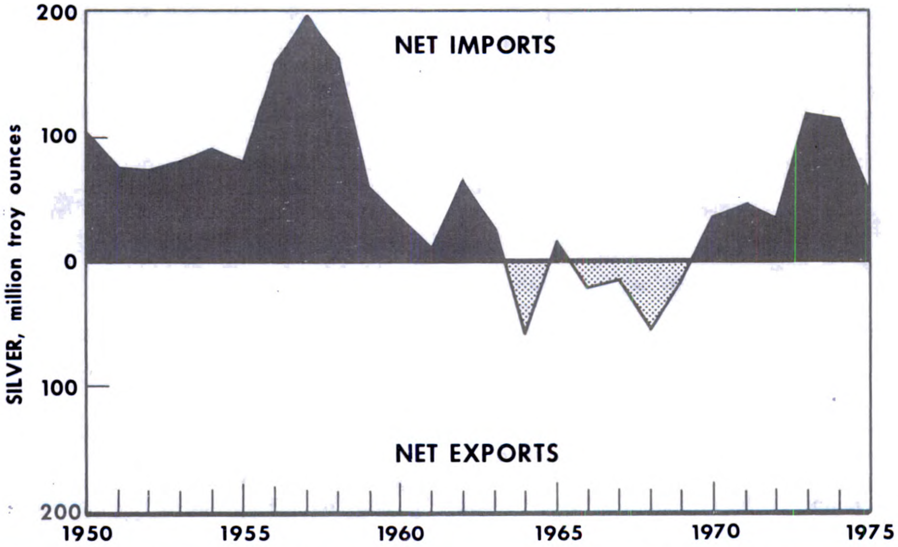

Figure 3.—Net exports or imports of silver, 1950–75.

Imports of silver totaled 90.4 million ounces compared with 133.4 million ounces in 1974. Refined bullion accounted for 68% of total imports; ore and concentrates, 23%; waste and scrap, 6%; and dore and precipitates the remainder. Imports in each of these import classes declined with bullion off 31%, and ores and concentrates off 39%. The principal source for imported silver in 1975 was Canada which supplied 34.3 million ounces equivalent to 38% of total imports. Mexico supplied 21.4 million ounces or 24% of total imports, and Peru supplied 17.7 million ounces or 20% of total imports. Australia, Honduras, Japan, and Yugoslavia, in the aggregate, supplied 14.0 million ounces or 15% of total imports. The remaining 3% was supplied by a number of countries including Chile, Southwest Africa, West Germany, the Philippines, and the Republic of South Africa. Most of the bullion imported in 1975 came from Canada, Mexico, and Peru. Ore and concentrates came mainly from Canada, Peru, Australia, Honduras, Mexico, and Southwest Africa. Canada accounted for most of the imported waste and scrap.

WORLD REVIEW

World mine production of silver in 1975, including centrally planned economy countries, declined 0.2% to 294.3 million ounces, as worldwide demand declined. The United States, Canada, Mexico, and Peru accounted for 51% of world output.

World consumption of silver in 1975 for industrial and coinage uses, exclusive of centrally planned economy countries, totaled 390.0 million ounces compared with 459.9 million ounces in 1974.[7] A 6% increase in use in coins was offset by a 17% decline in industrial use which accounted for 91% of total usage in 1975. Total consumption by market economy countries exceeded newly mined supply by 155.0 million ounces, according to Handy & Harman estimates. Secondary production supplied 45% of the difference, Indian stocks, 34%; demonetized coin, 13%; and U.S. and foreign governmental stocks, the remainder.

Australia.—Production of silver rose 8% to 23.5 million ounces. Development of

---

[7] Handy & Harman. The Silver Market, 1975. 60th Annual Review. 1975, 22 pp.

Mount Isa Mines, Ltd.'s, McArthur River lead-silver-zinc deposit in the Northern Territory, continued with the completion of underground access work and the 55-ton-per-day pilot plant. By yearend, it was reported that the deposit contained 315.0 million ounces of silver, but a satisfactory metallurgical process for extraction had not been developed. The main shaft of the company's new Hilton lead-zinc-silver mine was completed and equipped.

Canada.—Mine production of silver in 1975 declined 9% to 39.1 million ounces. Production of silver at the Kidd Creek mine of Texasgulf Canada Ltd. was 9.2 million ounces, about 12% below that of 1974.[8] At yearend, the mine contained an estimated 198.7 million ounces of silver above the 2,800-foot level. Diamond drilling in 1975, below the 2,800-foot level to delineate the ultimate depth of the ore deposit, continued to intersect ore. Texasgulf Inc. continued diamond drilling of its large base metal sulfide deposits at Izok Lake and Hood River, Northwest Territories. At yearend, the limited exploration had indicated 7 million tons of copper-zinc-lead ore containing 13 million ounces of silver at Izok Lake, and 820,000 tons of copper-zinc ore containing 0.7 million ounces of silver at Hood River. Further drilling was planned to determine the extent of both deposits.

Mine production of silver by United Keno Hill Mines, Ltd., declined 10% to 2.9 million ounces.[9] Ore reserves declined from 222,000 tons averaging 42 ounces of silver per ton to 208,000 tons averaging 37 ounces per ton. Production of silver at the new Sturgeon Lake mine, a joint venture between Sturgeon Lake Mines, Ltd., and Falconbridge Copper Ltd., was 0.977 million ounces from an ore reserve, at yearend 1975, of 1.8 million tons averaging 5.66 ounces of silver per ton.[10]

Seaforth Mines Ltd. began diamond drilling of the Porter Idaho silver property, near Stewart, British Columbia, which consists of three lode deposits, the Silverado, the Prosperity, and the Porter Idaho.[11] Very high gold and silver values per ton were reported from preliminary exploration in the Bathurst area of New Brunswick.[12] Gold values ranged from 19 ounces per ton to 32 ounces per ton, and silver values from 73 ounces per ton to 136 ounces per ton.

Production of silver from mines 12 and 6 of Brunswick Mining & Smelting Corp., Ltd., was 4.4 million ounces compared with 2.9 million ounces in 1974.[13] Reserves at both mines totaled about 100 million tons containing about 274 million ounces of silver. The Geco Division of Noranda Mines Ltd. reported production of 1.7 million ounces of silver in 1975. Ore reserves reportedly contained 42.7 million ounces of silver. Production of silver by Mattagami Lake Mines Ltd. and Mattabi Mines Ltd., with which Noranda had operating interests, totaled 2.4 million ounces. The silver content of the ore reserves of these mines totaled 36.2 million ounces.

Dominican Republic.—Rosario Dominicana, S.A., a subsidiary of Rosario Resources Corp., opened its new Pueblo Viejo base metal mine in June 1975.[14] Production of dore bullion included 109,465 ounces of silver and 195,941 ounces of gold. Reserves of oxide ore totaled 29.2 million tons containing 20 million ounces of silver and 3.7 million ounces of gold. An additional sulfide ore reserve of 21.1 million tons contained 17.7 million ounces of silver and 2.4 million ounces of gold. Development of the sulfide ore was contingent on development of a satisfactory metallurgical process to treat the ore.

El Salvador.—Agreement was reportedly reached between Canadian Javelin Ltd. and the Government for compensation to Javelin for mineral rights and assets of the Cerro Colorado silver-bearing copper deposits discovered by Javelin. Javelin continued to operate through a subsidiary, Minas San Cristobal, S.A., a gold-silver mine in El Salvador.

Honduras.—Production of silver in 1975 at the El Mochito mine of Rosario Resources Corp. totaled 3.5 million ounces compared with 3.7 million ounces in 1974. Ore reserves were increased during the year to 6.3 million tons containing 32.9 million ounces of silver and 18,970 ounces of gold. The reserves also contain lead, zinc, and copper.

Mexico.—Mine production of silver in 1975 was 38.0 million ounces. The extensive expansion of mines and plants, and exploration efforts begun in recent years continued in 1975. As a result of these activities Mexico may become the largest silver-producing nation in the world.

Lacana Mining Corp. was formed in September 1975 through the merger of Lacanex Mining Co. Ltd., Pure Silver Mines Ltd., and Tormex Mining Developers Ltd.[15] The new company has a 30% interest in the Las Torres silver-gold mining complex in Guanajuato, and a 40% interest in the La Encantada silver-lead mine in Coahuila in addition to mining operations outside Mexico. Annual silver production at the Las Torres complex was expected to reach 7.2 million ounces, when full production is reached in 1976, from an ore reserve containing 56 million ounces of silver and 434,000 ounces of gold. Silver production at the La Encantada mine in 1975, totaled about 946,000 ounces from a 3.9 million ton ore reserve containing 45.4 million ounces of silver. Expansion work at the La Encantada mine will increase annual production to 3.2 million ounces of silver.

Rosario Mexico, S.A. de C.V., 49%-owned by Rosario Resources Corp., continued its expansion program at the Huautla silver-lead mine in Morelos.[16] Scheduled for completion in late 1976, the new crushing plant will increase the production rate from 140 to 300 tons per day. Silver production in 1975 totaled about 510,000 ounces. At yearend, exploration and development work had increased silver reserves by 10% to 8.2 million ounces.

Explomin, S.A. de C.V., was conducting a feasibility study of the Real de Angeles property in Zacatecas.[17] Diamond drilling of the deposit indicated a reserve of 43 million tons averaging 2.3 ounces of silver per ton, equivalent to 99 million ounces. If put into production, the property could sustain a production rate of about 6 million ounces of silver per year.

Minera Mexicana de Avino, S.A., and Minera San Jose de Avino, S.A., operated its new copper-silver-gold mine north of Durango at near capacity in 1975.[18] The mill has a 500-ton-per-day capacity and processes ore from a 7.3-million-ton reserve containing 20.9 million ounces of silver. Canadian Barranca Corp. conducted exploration programs at the La Gloria mine, Torreon; the A Las Mil Una mine near San Pedro de Gallo; and the Tecolotes mine near San Luis del Cordero.[19] Sampling at the La Gloria mine indicated values of 8 ounces of silver per ton. At the Tecolotes mine, a 30,000-ton dump had an ore grade of 8.62 ounces of silver per ton. Canadian Barranca Corp. also had an interest in the El Palmarito mine, Sinaloa, where exploration and sampling indicated a reserve of 1 million tons containing 5.9 million ounces of silver.

Production of silver at the Real del Monte mine, Hildago, was 3.5 million ounces in 1975, well above the level of 1974. Reserves were estimated at about 25 million ounces. The Lampasos mine in Sonora began operation in April 1975 and production is expected to reach 1 million ounces by 1976.

Nicaragua.—Rosario Mining of Nicaragua, Inc., a subsidiary of Rosario Resources Corp., recorded silver production at the Rosita mine of 383,667 ounces in 1975.[20] The company continued to explore the area around the mine with encouraging results and in the Coco River area where diamond drilling outlined a large low-grade deposit of gold and silver.

Peru.—Mine production of silver in 1975 was 37.8 million ounces compared with 40.2 million ounces in 1974. Development of the Cuajone copper project continued and the property was expected to be in production in 1976. In addition to primary copper, large quantities of byproduct silver will be produced.

Philippines.—Johnson Matthey Chemicals Ltd. received financial backing for its planned gold and silver refinery at Quezon City.[21] The refinery will have an annual capacity of 450,000 ounces of silver and 600,000 ounces of gold.

TECHNOLOGY

The Bureau of Mines continued its studies to develop economic methods for recovering silver and associated metals from low-grade or refractory ores. Much of the research dealt with heap leaching, activated carbon gold-silver recovery methods, and elevated-temperature pressurized stripping of gold and silver loaded carbon. The carbon-in-pulp precious metal recovery process was successfully applied, on a pilot scale, to recover about 93% of the silver in 2-ounce-per-ton ore. Recovery rate in other tests exceeded 99%.

Research on gold-silver bearing siliceous fluxing ore, formerly used in copper refining in Montana, indicated that heap leaching followed by flotation of the residue recovered 89.7% of the gold and 84% of the silver, thereby offering the promise of continued operation for producers of the fluxing material. An improved stripping technique was developed for desorption of gold and silver from activated carbon. The process uses alkaline alcohol instead of hot caustic cyanide, and both the rate and extent of stripping were improved.

A promising technique was developed that extracted 91% of the total silver from calcines of a complex refractory oxide silver ore. Minus 100-mesh ground ore mixed with 5% NaCl was pelletized to form 10-mesh X 35-mesh furnace feed which was calcined at 600° C. Cyanidation of the calcine extracted 91% of the total silver.

In other research related to silver, gold telluride flotation concentrates were successfully treated by roasting with lime which allowed the gold to be removed by subsequent cyanidation without the emission of sulfur and tellurium oxides to the atmosphere. Bureau of Mines researchers conducted studies on electronic scrap processing with emphasis on mechanical beneficiation techniques to produce high-grade concentrated fractions of silver, gold, and other metals. It was found that silver could be recovered from stainless steel honeycomb aircraft scrap by shredding and electrolytic stripping.

The high price of silver and other precious metals has caused suppliers of electroplating solutions to produce solutions containing less precious metals and to replace pure precious metals with less expensive alloys.[22] Two new advances using silver were made in solar energy applications.[23] Silver-backed mirrors were developed that reflect 90% of solar light rays making possible the development of more than 17 watts of energy per square foot of mirror. In the other development, silver was used to coat the inside of a glass container which created a green house effect when light rays hit the inside surface and were reflected as long wavelength heat rays that remained within the container. Silver was used to purify water by killing bacteria which cause internal and external infections.[24]

A method was developed for refining silver matte to increase its silver, gold, and platinum-group metal content by reducing its copper, selenium, and tellurium content.[25] The process uses oxygen or oxygen-enriched air to volatilize selenium and tellurium from the molten matte and borax-silica flux to lower the copper content.

Table 2.—Mine production of recoverable silver in the United States, by month
(Thousand troy ounces)

Month	1974	1975

e Estimate. p Preliminary. r Revised.

[1] Recoverable content of ores and concentrates produced unless otherwise noted.

[2] In addition to the countries listed, Ghana, Mauritania, Thailand, and Turkey produce silver, but information is inadequate to make reliable estimates of output levels.

[3] Less than ½ unit.

[4] Includes production by the State mining company (COMIBOL) plus the exports of medium and small (private sector) mines.

[5] Smelter and/or refinery production.

[6] Output of Inyati mine only.

[7] Data represent recoverable content of Tsumeb Corp. Ltd. concentrates as well recovery from copper refinery sludges.

[8] Includes estimate for Klein Aub Koper Maatskappy Ltd.

[9] Includes recovery from copper refinery sludges.

Slag — Iron and Steel

By Walter Pajalich [1]

Combined output of both types of slag declined 15% in quantity and 7% in value below 1974 levels. Production of iron slag declined 15% in quantity and 7% in value, whereas that of steel slag decreased 18% in quantity and 20% in value. The tonnage of screened, air-cooled iron slag declined 15%, whereas the tonnage of granulated and expanded iron slag declined 16%.

The price per ton of iron slag increased 10% and steel slag decreased 3%. Despite a price increase, iron slag continued to be strongly competitive with similar construction materials.

A sharp gain in exports was recorded; volume rose 169% and value more than doubled. No imports of slag were reported in 1975.

DOMESTIC PRODUCTION

The volume of iron slag processed in 1975 was 25.3 million tons valued at $63.7 million, compared with 29.9 million tons valued at $68.1 million in 1974. Production of the principal type of iron slag—screened, air-cooled slag—totaled 21.6 million tons valued at $52.4 million, representing declines of 15% and 7%, respectively, from the production and value levels of 1974. Output of unscreened, air-cooled material declined slightly. Of the 12% of iron slag processed using water techniques, granulated slags declined to 1.8 million tons valued at $4.3 million, whereas expanded slags declined to 1.3 million tons valued at $5.9 million. Steel slag declined 18% to 7.3 million tons and the value declined 20% to $9.0 million.

A total of 50 companies operated 74 air-cooling, 7 expanding, and 10 granulating slag plants. Slag-encrusted iron reclaimed magnetically by slag processors for resmelting totaled 2,667,929 tons. The 1,843 plant and yard employees in the industry worked 2,486,397 man-hours.

About 22% of all slag was produced in Pennsylvania, 21% in Ohio, and 24% in Illinois, Indiana, and Michigan. The remaining 33% came from Alabama, California, Colorado, Kentucky, Maryland, New York, Texas, Utah, and West Virginia.

CONSUMPTION AND USES

As in past years, nearly all of the slag produced in the manufacture of pig iron and steel was either recycled or used by the construction industry.

A 15% decrease in overall consumption of screened, air-cooled iron slag was accounted for principally by a 5% decrease in shipments for highway and airport construction, a 44% decrease in use for portland-cement concrete construction, and a 31% decrease in bituminous construction use. Together, these uses accounted for 72% of the total consumption of this type of iron slag. Most recorded uses declined for the year. Consumption of unscreened, air-cooled iron slag declined 6%. The principal use, highway and airport construction, recorded an 8% decline, and numerous minor applications nearly disappeared.

The volume of granulated iron slag consumed declined 14% and that of expanded iron slag declined 17%. In its principal use, highway construction, granulated slag was down 30%. Some uses for granulated slag recorded gains. In the principal use for expanded slag, concrete block manufacture, consumption was down 17%. All other significant uses of expanded slag recorded declines. No expanded iron slag was reported for use in manufacture of cement.

Consumption of steel slag was 18% below that of 1974, and was characterized by fluctuations throughout its range of uses. Use as paved-area base, miscellaneous base, and bituminous mixes was 33% less in 1975. There was a significant increase in use as highway base. No steel slag was used in agriculture in 1975.

Laboratory research programs indicated that a satisfactory base stabilization process has been developed using ground pelletized blast furnace slag (30%) and air-cooled blast furnace slag (70%) with suitable mixture of water. Pelletizing involves expanding the molten blast furnace slag under water sprays on a feed plate and passing this pyroplastic material over a pelletizing drum to form glassy pellets with cementitious properties. The cementitious nature of such ground pelletized slag makes it a viable alternative to the use of asphalt and portland cements for base stabilization applications and brick manufacture, with a considerable saving of energy.[2]

PRICES

Slag producers reported generally rising prices in 1975 in nearly all slag applications. The overall average f.o.b. plant price for iron slag rose from $2.28 per ton in 1974 to $2.51 per ton in 1975. The price of steel slag dropped slightly from $1.26 per ton to $1.23 per ton.

The average price of screened, air-cooled iron slag in 1975 was $2.43 per ton compared with $2.21 per ton in 1974. For aggregate use, the average price rose 11% to $2.52 per ton; for railroad ballast, 9% to $1.86 per ton; and mineral wool, 26% to $3.14 per ton. A 28% increase in the price per ton of unscreened slag used for highway construction was recorded in 1975.

The average price of granulated and expanded slags was 15% and 11% higher, respectively, than that of 1974. The price of granulated slag used in highway and airport construction, the principal use, rose 28% to $2.12 per ton; prices for other major uses generally increased. Price increases were recorded for expanded slag in the manufacture of concrete block and lightweight concrete.

Highway, paved-area, and miscellaneous base uses accounted for about 84% of the total use of steel slag. Price decreases for steel slag ranged from $0.10 per ton to $0.53 per ton in 1975. Increases ranged from $0.10 to $0.30 per ton. Steel slag used for railroad ballast decreased $0.15, highway base $0.10, bituminous mixes $0.38, and other uses $0.53 per ton. Material used for paved-area base increased $0.30 per ton and miscellaneous base or fill increased $0.10 per ton.

FOREIGN TRADE

Exports of iron and steel slag increased sharply to 139,516 tons valued at $5.5 million. Nevertheless, exports were equivalent to only 0.4% of the quantity and 8% of the value of domestic production of slag.

The high unit value for exported slag, $39.46 per ton on the average, was indicative of the high metal content of the material. Increased exports to Canada and Japan accounted for nearly all of the increase in quantity and value of exports. About 88% of the exported material went to these countries; Canada alone accounted for 55%. Other countries receiving significant quantities were Belgium-Luxembourg, Mexico, and Guatemala.

Imports of slag in 1975, if any, were not reported in official statistics.

Sodium and Sodium Compounds

By Charles L. Klingman [1]

The year 1975 was not a normal one for the production and consumption of sodium compounds. Smaller demands in nearly all uses restricted production, but at the same time prices were significantly higher. A summary of the quantity and value, based on yearend prices, of natural sodium compounds and metallic sodium produced in 1975 is as follows:

	Production (thousand short tons)	Value (thousand dollars)
Soda ash	4,328	182,620
Sodium sulfate	667	27,667
Metallic sodium	144	[e] 60,187

[e] Estimate.

Naturally derived soda ash and sodium sulfate fared better than the synthetic or byproduct varieties. Natural sodium sulfate production dropped only 2% from the 1974 figure, compared with a 16% loss for the byproduct salt cake. Naturally derived soda ash increased 7% in contrast with a 20% decline in Solvay soda ash production. There were two closures of Solvay soda ash plants in 1975, while all producers of natural soda ash were enlarging their plants. Production capacity for natural soda ash was scheduled to rise 54% to about 10 million tons per year by 1980.

Exports of soda ash remained high at 7.8% of production. Importation of sodium sulfate was about 20% of the apparent consumption. Total exports of both salts were higher in value than total imports by $39 million.

DOMESTIC PRODUCTION

Overall soda ash production in 1975 decreased 6%, but the natural product derived from trona or brine showed an increase of 7%. Synthetic or Solvay soda ash continued to decline by dropping 20% below the 1974 production level. In 1975, natural soda ash accounted for 61% and Solvay carbonate fell to 39% of the total. Table 2 shows the trend over the past 10 years from Solvay to natural soda ash.

There were two closings of major Solvay soda ash plants in 1975: Allied Chemical Corp.'s plant at Baton Rouge, La., in May with a nominal capacity for 785,000 tons per year and Olin Corp.'s plant at Lake Charles, La., in September with a nominal capacity for 350,000 tons per year. The four remaining Solvay plants in the United States had a combined nominal capacity for 2.9 million tons per year.

At yearend 1975, four companies operating five plants for production of natural soda ash had a nominal capacity of 6.5 million tons per year, or 69% of the total U.S. soda ash capacity. Announced expansions in plant capacity reportedly will increase the totals by yearend 1976 to 7.5 million tons, and at yearend 1977 to 8.8 million tons per year. Texasgulf, Inc., which is scheduled to open its new million-ton-per-year mine and plant in 1976 (included in the previous figures), had plans for doubling its output when practical after its first unit is operational. Stauffer Chemical Co. also announced its intention to raise capacity another 200,000 tons per year by 1977. This will place the natural soda ash capacity for the United States at about 10.0 million tons per year. Domestic demand for soda ash was not predicted to increase as fast as production capacity, so overcapacity may result, especially if the present Solvay plants remain in operation. Increased exportation of soda ash may relieve an overcapacity situation.

---

[1] Physical scientist, Division of Nonmetallic Minerals.

Allied Chemical Corp. had a 6-week strike at its Green River, Wyo. soda ash plant which ended September 12, 1975.

Soda ash stocks on hand increased about 18,000 tons during 1975.

There was a decrease of 9% in total sodium sulfate production, with the manufactured variety showing a 16% drop and the natural product displaying a reduction of only 2%. In 1975, there were three companies operating five plants in California, Texas, and Utah for the production of natural sodium sulfate. The sodium sulfate production of U.S. Borax & Chemical Corp. will be excluded from the total after this year because its sulfate is essentially a byproduct of boric acid manufacture rather than an earth-derived compound. Kerr-McGee Chemical Corp. was in the process of building a new plant at Searles Lake, Calif., which is scheduled to increase its sodium sulfate capacity by 150,000 tons per year by yearend 1977.

Byproduct sodium sulfate was supplied by 18 companies operating 23 plants in 15 States with a nominal production capacity of 754,000 tons per year. About three-fourths of these plants were located east of the Mississippi River.

In the fall of 1975, the Bureau of Mines started publishing monthly Mineral Industry Surveys showing production of naturally derived soda ash and sodium sulfate in the United States. The January 1976 issue contained a 6-year monthly historical tabulation of this production.

Production of metallic sodium fell 17% to 143,989 tons in 1975. Table 4 shows the trend in production and in the price of metallic sodium for the past 10 years.

1975	148,989	• 20.90

• Estimate.

A list of U.S. producers of natural sodium compounds and metallic sodium follows:

Product and company	Plant location	State	Source of sodium
Soda ash:			
Kerr-McGee Chemical Corp	Trona	California	Dry lake brine.
Do	Westend	do	Do.
Allied Chemical Corp	Green River	Wyoming	Underground trona.
FMC Corp	do	do	Do.
Stauffer Chemical Co	do	do	Do.
Sodium sulfate:			
Kerr-McGee Chemical Corp	Trona	California	Dry lake brine.
Do	Westend	do	Do.
U.S. Borax & Chemical Corp	Boron	do	Open pit mining.
Ozark-Mahoning Co	Brownfield	Texas	Subterranean brine.
Do	Seagraves	do	Do.
Great Salt Lake Minerals & Chemicals Corp.	Ogden	Utah	Salt lake brine.
Metallic sodium:			
E. I. du Pont de Nemours & Co	Niagara Falls	New York	Salt.
Do	Memphis	Tennessee	Do.
Ethyl Corp	Baton Rouge	Louisiana	Do.
Do	Houston	Texas	Do.
RMI Co	Ashtabula	Ohio	Do.

CONSUMPTION AND USES

The percent usage of soda ash and sodium sulfate as given in the Chemical Marketing Reporter[2] are quoted below:

Industry	Percent of demand	
	Soda ash	Sodium sulfate
Pulp and paper	7	70
Glass	47	--
Detergents	6	20
Chemicals	25	--
Water treatment	3	--
Other and exports	12	10

The Bureau of Mines does not conduct direct surveys of consumers of sodium compounds, so information on consumption was derived from secondary sources. In 1975, however, some of the sodium-consuming industries were quite depressed and did not utilize as much of the sodium-bearing materials as they did in 1974.

The pulp and paper industry required only 86% of the previous year's soda ash and sodium sulfate requirements. Window glass and glass fibers production was also below 1974 levels. Glass for bottles and other containers, however, held up very well in 1975.

Production of plastics and resin products was down 30% from the 1974 level, and miscellaneous inorganic chemicals were lower by 20% to 25%. Production of soaps and detergents was up an estimated 9% over 1974. The demand for antiknock compounds in gasoline was reduced in 1975 by the mandatory use of catalytic converters on most new automobiles. The consumption of metallic sodium required in the manufacture of antiknock compounds was consequently reduced 17%.

Production of chlorine-caustic soda was of significance because of the interchangeability of soda ash and caustic soda. During 1975, there was a sharp drop in demand for chlorine because of declines in chlorinated solvents, chemicals, and paper products. This reduced the availability of caustic soda, coproduct of chlorine production and allowed soda ash to penetrate caustic soda markets.

PRICES

Prices of natural soda ash and natural sodium sulfate were derived from the Bureau of Mines annual survey. Producers were asked to place a value on their finished products in bulk at the dock without transportation charges. The average prices derived from these surveys follow:

	Value, dollars per short ton		Change, %
	1974	1975	
Bulk soda ash	33.87	42.20	+25
Bulk sodium sulfate	23.99	41.48	+73

A tabulation of prices as quoted in trade journals for various grades and packaging of soda ash, sodium sulfate, and metallic sodium follows:

		1974[1]	1975
Sodium carbonate (soda ash):			
Light, paper bags, carlots, works	per ton	\$56.00–74.00	\$57.00–71.00
Light, bulk, carlots, works	do	54.00–64.00	57.00–64.00
Dense, paper bags, carlots, works	do	42.00–42.50	57.00–71.00
Dense, bulk, carlots, works	do	42.00–54.00	47.00–49.00
Sodium sulfate (100% Na_2SO_4):			
Technical detergent, rayon-grade, bags, carlots	do	43.00–46.00	60.00–65.00
Technical detergent, rayon-grade, bulk, works	do	33.00–38.00	55.00
Domestic salt cake, bulk, works[2]	do	31.00	60.00
National Formulary (N.F. XII), drums	per pound	.23½	.28½
Metallic sodium:			
Bricks, carlots, works	do	.30	.30
Fused, lots 18,000 pounds and more, works	do	.26½–.27½	.26½–.27½
Bulk, tank, works	do	.18¾	.22½

FOREIGN TRADE

In 1975 soda ash exports from the United States amounted to 552,000 tons, which was 7.8% of the total production. Only 3,000 tons of soda ash was imported. Forty-four percent of U.S. exports went to other North American countries, 36% to South America, 14% to Asia and Oceania, 5% to Africa, and 1% to Europe.

The United States imported about 20% of its sodium sulfate demand, two-thirds of which came from Canada and one-third from Belgium-Luxembourg. It exported 6% of its sodium sulfate production, the bulk of which went to Oceania and Asia.

The value of exports of sodium compounds exceeded the value of imports by over $39 million. The Department of Commerce, which obtained original data on soda ash exports under Schedule B, No. 5147005, nominally excluded the naturally derived product. Some exported natural soda ash may, therefore, have been classified in a basket category and thereby be excluded from Federal Bureau of Mines export records.

Table 5.—U.S. exports of sodium carbonate and sodium sulfate
(Thousand short tons and thousand dollars)

Year	Sodium carbonate		Sodium sulfate	
	Quantity	Value	Quantity	Value
1973	425	16,064	45	2,049
1974	564	34,156	51	3,250
1975	552	45,985	77	6,144

Table 6.—U.S. imports for consumption of sodium sulfate
(Thousand short tons and thousand dollars)

	Quantity	Value
Soda ash	2	341
Sodium bicarbonate	1	79
Total	3	420

WORLD REVIEW

Tables 8 and 9 show world production of soda ash and sodium sulfate by countries. From these tables it can be seen that the United States produced 98% of the world's natural soda ash, and the United States and Canada together produced 56% of the world's natural sodium sulfate. The five top-ranking soda ash producing nations of the world, in order, were: the United States, the U.S.S.R. France, West Germany, and Japan. The five top-ranking nations in the production of sodium sulfate were: the United States, the U.S.S.R., Canada, Mexico, and Japan.

In 1975, the consumption of soda ash in Europe was on the increase primarily because of reduced production of chlorine and its coproduct, caustic soda. There were environmental pressures on the chlorine derivatives in Europe as well as in the United States, and chlorine production was restricted accordingly. Soda ash was the logical replacement for caustic soda in the manufacture of chemicals and alumina.

The Akzo soda ash plant at Delfzijl, Netherlands announced an increase in its soda ash capacity by 30% to be completed by 1977. Solvay & Cie. S.A. was also considering doubling its soda ash production to 800,000 tons per year at Couillet, Belgium.

e Estimate. p Preliminary. r Revised.

[1] In addition to the countries listed, a number of nations are either known or believed to have produced sodium carbonate, but production is unreported, and available general information is inadequate for the formulation of reliable estimates of output levels. Notable among the producing countries not listed are Australia, Canada, the People's Republic of China, and the United Kingdom.

[2] Quantity reported for sodium carbonate in 1972 has been revised by official sources from 164,000 short tons to 181,000 short tons.

[3] Sold or used by producers.

[4] Production for sale only; excludes output consumed by producers.

e Estimate. p Preliminary. r Revised.

[1] In addition to the countries listed, the People's Republic of China, Poland, Romania, and the United Kingdom are assumed to have produced manufactured sodium sulfate, and other unlisted countries may have produced this commodity, but production figures are not reported and available general information is inadequate for the formulation of reliable estimates of output levels.

[2] Natural mine output, excluding byproduct output from the nitrate industry which is reported under manufactured.

[3] Conjectural estimates based on 1968 information on natural sodium sulfate only.

[4] Sold or used by producers.

[5] Byproduct of nitrate industry.

[6] Quantities of manufactured sodium sulfate credited to Spain are reported in official sources in such a way as to indicate that they are in addition to the quantities reported as mined (reported in this table under natural) but some duplication may exist.

[7] Derived approximate figure; difference between reported total sodium sulfate production (natural and manufactured, undifferentiated) and reported quantity of natural sodium sulfate sold or used by producers.

Argentina.—At the end of 1975, plans were being finalized to build a Solvay plant capable of producing 220,000 tons of soda ash per year near San Antonio Oeste in southern Argentina. This will be Argentina's first soda ash facility and will be a joint effort between the Argentine firm of Alcalis de la Patagonia and PPG Industries Inc. of the United States. The building contractor is Ferrostaal, A.G. of West Germany. The proposed plant is adjacent to one of the world's largest salt deposits.

India.—The government of India banned the exportation of soda ash from that country in the fall of 1975. There were protests from the Indian soda ash producers, and unsold stocks increased to 50,000 tons by December 1975. Prices of domestic soda ash and sodium bicarbonate were subsequently reduced.

Italy.—A new complex, which had an annual capacity of 260,000 tons of soda ash and sodium bicarbonate, was opened at Termini Imerese, Sicily, in 1975 by Orinoco. Capital costs of the project were $56.9 million.

U.S.S.R.—Soda ash production in the U.S.S.R. in the first half of 1975 was 8% higher than a comparable period of 1974, up to 2.5 million short tons.

TECHNOLOGY

A major soda ash producer developed a "double alkali" system for scrubbing sulfur dioxide from stack gases. The new procedure, which utilized a concentrated solution of sodium salts instead of limestone, will be tried in an industrial furnace in Pottstown, Pa.[3]

---

[3] Chemical & Engineering News. Concentrates. Firestone Will Evaluate FMC's Scrubbing System. V. 54, No. 2, Jan. 1, 1976, p. 30.

A waste solution from papermaking, which contained both soda ash and sodium sulfate, was retorted at high temperature and reduced to a mixed salt which was usable as an ingredient in glassmaking.

The Energy Research and Development Administration (ERDA) requested bids on an experimental metallic-sodium-filled cable, complete with splices and terminations, to carry a 138,000-volt current underground around Wolf Mill, Pa. If such a cable should be technologically and economically feasible, there would be a large new market for metallic sodium.

Stone

By Avery H. Reed [1]

Production of the stone industry declined from the record highs set in 1973–74. Output of dimension stone declined 27% to 1.40 million tons valued at $98.6 million. Production of crushed stone fell 13% to 901 million tons valued at $2.02 billion.

Leading stone producers were Vulcan Materials Co., 90 quarries; Martin Marietta Corp., 114 quarries; United States Steel Corp., 15 quarries; Lone Star Industries, Inc., 26 quarries; General Dynamics Corp., 7 quarries; U.S. Forest Service, 524 quarries; Medusa Aggregates Co., 48 quarries; Standard Industries, Inc., 19 quarries; The Flintkote Co., 28 quarries; and Mid-South Pavers, Inc., 17 quarries. These 10 companies operated 888 quarries and accounted for 22% of the total stone production.

Stone was produced in every State except Delaware. There were 2,259 companies, with 5,917 quarries or underground mines. Average output per company was 400,000 tons. Average production per quarry was 153,000 tons.

Since 1945 the total value of dimension stone production has multiplied five times, from $20 million to $100 million. Since 1945, the total output of crushed stone has multiplied seven times, from 150 million tons to 1 billion tons in 1974.

Classification.—The Bureau of Mines classifies stone into two categories, crushed and dimension; and into nine kinds—granite, limestone, marble, marl, sandstone, shell, slate, traprock, and miscellaneous.

The category classifications are not exact; some crushed stone may be in large pieces, such as riprap, and some dimension stone may be in small pieces, such as art objects or carvings. The dimension stone industry is concerned with cutting or shaping stone to a certain size, and waste or scrap from processing dimension stone may be a part of the crushed stone industry.

Classification by kind is also difficult. Granite may include metamorphic gneisses or syenites. Limestone may be pure calcium carbonate, but may be bituminous, dolomitic, or silicious. Marble may include any calcareous rock that will polish. Marl may range from low to high in shale or clay

---

Imports for consumption (value)	$33,643	$43,436	$48,678	$51,631	$45,625

[r] Revised.
[1] Data do not add to total shown because of independent rounding.

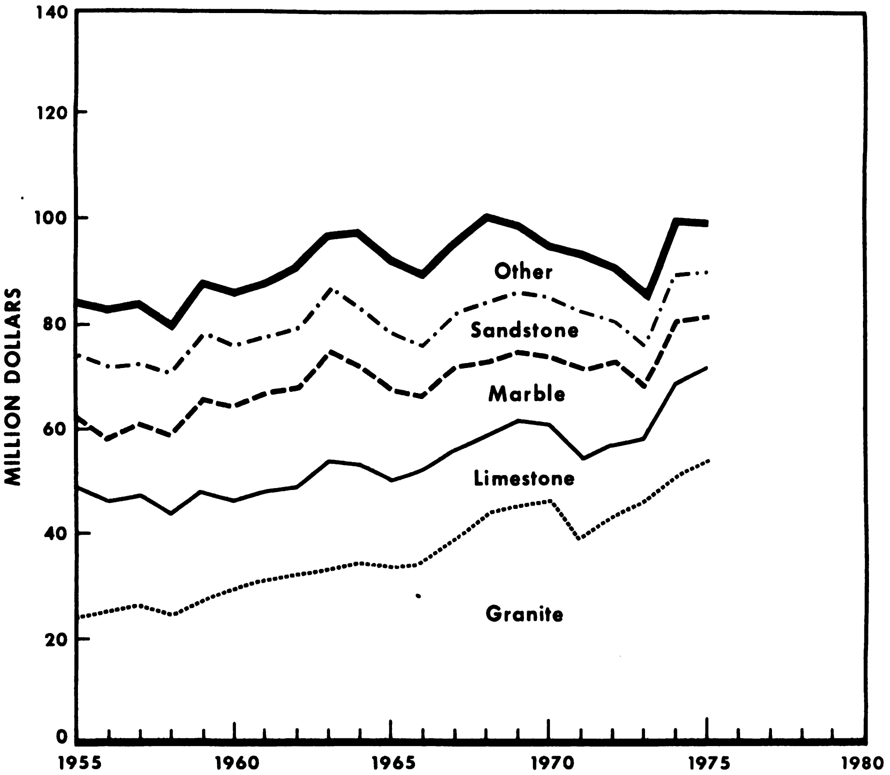

Figure 1.—Value of dimension stone sold or used by producers in the United States, by kind.

content. Sandstone may be calcareous, quartz or quartzite, silt or conglomerate. Miscellaneous stone includes aa, lava, schist, and any other stone not included in the aforementioned categories.

The Bureau of Mines generally accepts the classification reported by producers.

Deposits of unconsolidated materials, including beach sands, are generally classified as sand and gravel, regardless of chemical content. However, many deposits of stone are relatively soft, and may be mined without blasting. Natural sand deposits are classified as sand and gravel, but manufactured sand (stone sand) is classified as stone.

The Bureau of Mines canvass of dimension stone does not include processors of purchased rough stone. All producers are covered; if the producer sells rough stone to a processor, it is tabulated as rough stone; if the producer processes finished stone, only the finished stone is tabulated and the rough stone is deducted.

Capacity figures and stocks are not available. Inventories on hand at quarries and plants are estimated at about 1 month's supply, or 100 million tons.

DOMESTIC PRODUCTION

Dimension Stone.—Dimension stone was produced in 43 States. Leading States were Indiana, Georgia, Vermont, Ohio, and Pennsylvania, which together accounted for 56% of the total output. Of the total production, 43% was granite, 30% was

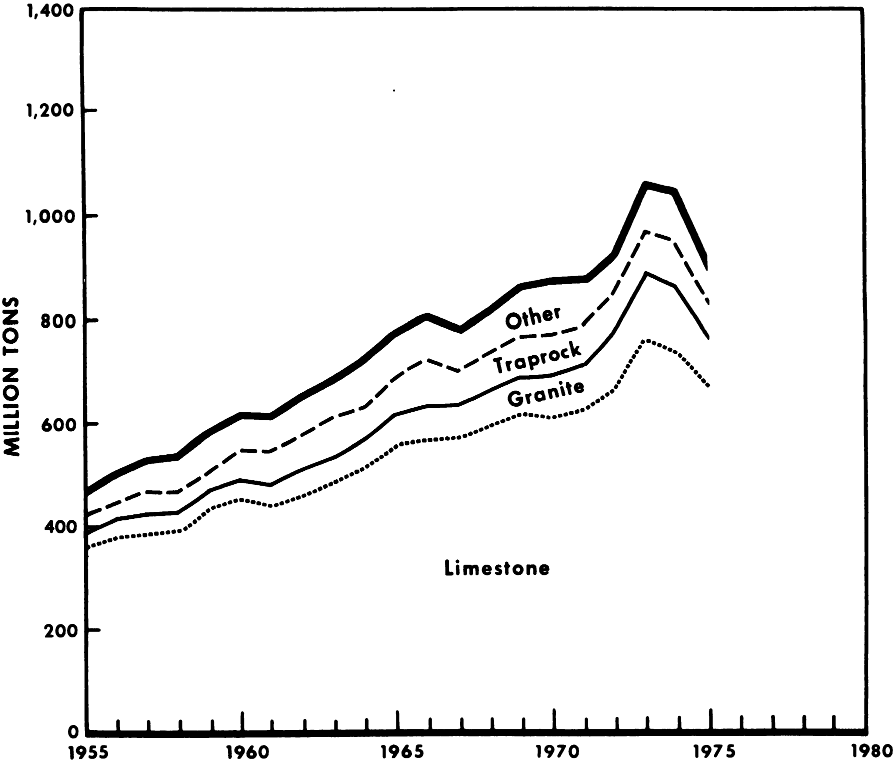

Figure 2.—Crushed stone sold or used by producers in the United States, by kind.

limestone, and 16% was sandstone. Leading companies were Coggins Granite Industries Inc., and Rock of Ages Corp. There were 309 companies; average output per company was 4,500 tons valued at $320,000. Total output of dimension stone was 1.40 million tons valued at $98.6 million.

Crushed Stone.—Crushed stone was produced in every State except Delaware. Leading States were Illinois, Pennsylvania, Texas, Missouri, and Ohio, which accounted for 30% of the total output. Of the total production, 74% was limestone, 10% was granite, and 9% was traprock. There were 2,001 companies; average output per company was 450,000 tons valued at $1.01 million. Leading companies were Vulcan Materials Co., Martin Marietta Corp., and United States Steel Corp. Total output of crushed stone was 901 million tons valued at $2.02 billion.

LIMESTONE

Dimension.—Dimension limestone was produced by 67 companies in 18 States. Leading producing States were Indiana, Wisconsin, Alabama, Kansas, and Iowa, which accounted for 87% of the total output. Leading companies were Victor Oolitic Stone Co. and Indiana Limestone Co., Inc. Total output declined 19% to 420,000 tons valued at $18.3 million. Average production per company was 6,300 tons valued at $272,000.

Crushed.—Crushed limestone and dolomite was produced by 1,390 companies in 46 States. Leading States were Illinois, Texas, Pennsylvania, Missouri, and Ohio, which accounted for 38% of the total output. Leading companies were Vulcan Materials Co. and Martin Marietta Corp. Total limestone output declined 11% to 666 million tons. Average production per company was 480,000 tons valued at $1 million. There was no crushed limestone production in Delaware, Louisiana, New Hampshire, and North Dakota.

GRANITE

Dimension.—Dimension granite was produced by 83 companies in 21 States. Leading States were Georgia, Vermont, New Hampshire, Massachusetts, and South Dakota, which accounted for 79% of the total output. Leading companies were Coggins Granite Industries and Rock of Ages Corp. Output declined 8% to 604,000 tons valued at $54 million. Average production per company was 7,300 tons valued at $651,000.

Crushed.—Crushed granite was produced by 172 companies in 33 States. Leading States were Georgia, North Carolina, Virginia, South Carolina, and Arkansas, which accounted for 80% of the total output. Leading companies were Vulcan Materials Co. and Martin Marietta Corp. Output declined 20% to 94.3 million tons valued at $217 million. Average production per company was 548,000 tons valued at $1.26 million.

TRAPROCK

Dimension.—Dimension traprock was produced by five companies in Hawaii, Washington, California, Virginia, and New Jersey. Leading companies were J. W. Glover, Ltd., and Heatherstone, Inc. Output was about the same as in 1974, 1,230 tons valued at $13,000. Average production per company was only 250 tons valued at $2,700.

Crushed.—Crushed traprock was produced by 288 companies in 25 States. Leading States were Oregon, New Jersey, Connecticut, Hawaii, and Washington, which accounted for 60% of the total output. Leading producers were the U.S. Forest Service and Standard Industries, Inc. Total output declined 19% to 78.4 million tons valued at $193 million. Average production per company was 273,000 tons valued at $669,000.

SANDSTONE

Dimension.—Dimension sandstone was produced by 94 companies in 27 States. Leading States were Ohio, Pennsylvania, New York, Georgia, and Maryland, which accounted for 74% of the total output. Leading producers were The Flintkote Co. and Briar Hill Stone Co. Output declined 12% to 229,460 tons valued at $8 million. Average production per company was 2,400 tons valued at $85,000.

Crushed.—Crushed sandstone, quartz, and quartzite was produced by 197 companies in 35 States. Leading States were Arkansas, Pennsylvania, California, Alaska, Ohio, and Michigan, which accounted for 64% of the total output. Leading producers were the U.S. Forest Service and Ottaway Silica Co. Output declined 13% to 27.1 million tons valued at $77.2 million. Average production per company was 138,000 tons valued at $392,000.

MARBLE

Dimension.—Dimension marble was produced by 15 companies in 13 States. Leading States were Vermont, Georgia, Tennessee, Alabama, and Montana, which accounted for 83% of the total output. Leading companies were Vermont Marble Co. and Georgia Marble Co. Output declined 32% to 50,000 tons valued at $9.5 million. Average production per company was 3,300 tons valued at $635,000.

Crushed.—Crushed marble was produced by 19 companies in 13 States. Leading States were Alabama, Georgia, North Carolina, Virginia, and Wyoming, which accounted for 91% of the total output. Leading companies were Georgia Marble Co. and Moretti-Harrah Marble Co. Output declined 13% to 1.5 million tons valued at $22.6 million. Average production per company was 77,000 tons valued at $1.19 million.

SLATE

Dimension.—Dimension slate was produced by 32 companies in 7 States. Leading States were Pennsylvania, Vermont, Virginia, North Carolina, and New York. Leading producers were A. Dalley & Sons and Stoddard Slate Co., Inc. Output declined 21% to 61,900 tons valued at $7.5 million. Average production per company was 1,900 tons valued at $233,000.

Crushed.—Crushed slate was produced by nine companies in Virginia, Georgia, Arkansas, New York, and North Carolina. Leading producers were Georgia Lightweight Aggregate Co. and Solite Corp. Output declined 45% to 761,000 tons valued at $4.9 million. Average production per company was 85,000 tons valued at $549,000.

SHELL

Shell was produced by 17 companies in Louisiana, Texas, Alabama, Florida, South Carolina, California, and Virginia. Leading companies were Radcliff Materials, Inc., and Parker Bros. & Co., Inc. Output declined 15% to 15.5 million tons valued at $52.7 million. Average production per company was 909,000 tons valued at $3.1 million.

CALCAREOUS MARL

Marl was produced by 31 companies in 7 States. Leading States were South Carolina and Mississippi, which accounted for 78% of the total output. Leading companies were Santee Portland Cement Co. and Giant Portland Cement Co. Output declined 10% to 3.50 million tons valued at $4.87 million. Average production per company was 113,000 tons valued at $157,000.

MISCELLANEOUS STONE

Dimension.—Other kinds of dimension stone were produced by 23 companies in 10 States. Leading States were Maryland, Hawaii, Pennsylvania, Virginia, and New Jersey, which accounted for 89% of the total output. Leading producers were Joe's Moss Rock, Inc. and Stoneyhurst Quarries. Output declined 89% to 37,000 tons valued at $1.28 million. Average production per company was only 1,600 tons valued at $56,000.

Crushed.—Other crushed stone was produced by 89 companies in 28 States. Leading States were Pennsylvania, California, Alaska, Utah, and Oklahoma, which accounted for 82% of the total output. Leading producers were the U.S. Forest Service and Eureka Stone Quarry, Inc. Output declined 23% to 14.2 million tons valued at $31 million. Average production per company was 159,000 tons valued at $348,000.

CONSUMPTION AND USES

Stone was consumed in every State. Some dimension stone was shipped to many States for use in buildings or as monuments. Most crushed stone was consumed in the State where it was produced. Many industries have grown up in the vicinity of stone quarries, such as cement mills or lime plants.

In the following descriptions of individual uses, output is considered to be the equivalent of consumption.

Dimension.—Dimension stone was used mainly for building and monumental stone. Stone sold as rough blocks decreased 11% to 293,600 tons valued at $9.6 million. Rough monumental stone output decreased 4% to 280,000 tons valued at $15.5 million. Output of cut, dressed building stone decreased 1% to 127,300 tons valued at $22.9 million. Output of curbing increased 1% to 123,000 tons valued at $7.8 million. Rubble production was 106,800 tons valued at $1.18 million. These five uses accounted for 66% of the total production.

Crushed.—Crushed stone was used mainly for building and road construction. It was also used in basic chemical industries, and for many other uses. Dense-graded roadbase stone production declined 12% to 216 million tons valued at $440 million. Output of coarse concrete aggregate declined 14% to 120 million tons valued at $261 million. Output of other construction aggregate and roadstone declined 9% to 117 million tons valued at $265 million. Production of stone used in cement decreased 17% to 95.5 million tons valued at $167 million. Output of bituminous aggregate declined 13% to 89.6 million tons valued at $226 million. These five uses accounted for 71% of the total production.

[1] Includes carbon dioxide (1975), porcelain, flour (slate), stucco, disinfectant, and other uses.

[2] Data may not add to totals shown because of independent rounding.

LIMESTONE

Dimension.—Dimension limestone was used mainly as building stone. Sales of rough limestone blocks declined 21% to 162,400 tons valued at $4.04 million. Output of house stone veneer declined 12% to 55,600 tons valued at $2.3 million. Production of sawed, dressed building stone declined 16% to 54,500 tons valued at $3.4 million. Production of cut building stone increased 5% to 54,300 tons valued at $6.9 million. Output of rubble declined 54% to 36,700 tons valued at $427,000. These five uses accounted for 87% of the total output.

Crushed.—Output of dense-graded roadbase stone declined 10% to 152 million tons valued at $290 million. Production of concrete aggregate declined 10% to 94.3 million tons valued at $199 million. Output of crushed limestone for cement declined 16% to 88.3 million tons valued at $151 million. Production of other aggregates and roadstone declined 5% to 73.1 million tons valued at $151 million. Output of bituminous aggregate declined 7% to 57.8 million tons valued at $140 million. These five uses accounted for 70% of the total output of crushed limestone.

W Withheld to avoid disclosing individual company confidential data; included with "Other uses" and "Other States."

[1] Includes all aggregates.

[2] Includes dead-burned dolomite.

[3] Includes Massachusetts, New Jersey, Oregon, Rhode Island, South Carolina, and States indicated by symbol W.

[4] Data may not add to totals shown because of independent rounding.

[5] Includes stone sand, alkalies, fill, glass, other fillers, other uses, and uses indicated by symbol W.

GRANITE

Dimension.—Dimension granite was used mainly for monumental and building stone. Output of rough monumental stone declined 5% to 279,400 tons valued at $15.5 million. Production of curbing increased 1% to 122,400 tons valued at $7.76 million. Sales of rough granite blocks increased 30% to 60,800 tons valued at $2.21 million. Output of dressed monumental stone increased 37% to 46,400 tons valued at $14.1 million. Production of cut building stone increased 14% to 38,600 tons valued at $12.2 million. These five uses accounted for 91% of the total output of dimension granite.

Crushed.—Output of dense-graded roadbase stone declined 14% to 30.1 million tons valued at $67.8 million. Production of concrete aggregate declined 26% to 15.9 million tons valued at $36.9 million. Output of bituminous aggregate declined 17% to 15.1 million tons valued at $37.9 million. Production of other aggregates and roadstone declined 27% to 12.4 million tons valued at $28.2 million. Output of crushed granite for use as railroad ballast declined 5% to 7.43 million tons valued at $15.8 million. These five uses accounted for 86% of the total output of crushed granite.

Total [2]	118,560	238,140	94,258	216,990

[r] Revised.

[1] Includes asphalt filler, cement (1974), building products (1974), and other uses.

[2] Data may not add to totals shown because of independent rounding.

TRAPROCK

Dimension.—Dimension traprock was used for rubble (88%), sold as rough blocks, and used as rough building stone.

Crushed.—Output of dense-graded roadbase stone declined 15% to 19.2 million tons valued at $43.6 million. Production of other aggregates and roadstone declined 29% to 17.3 million tons valued at $45.8 million. Output of bituminous aggregate declined 14% to 12.5 million tons valued at $35.8 million. Production of surface treatment aggregate increased 54% to 7.4 million tons valued at $16.4 million. Output of riprap declined 19% to 7.07 million tons valued at $11.0 million. These five uses accounted for 81% of the total output of crushed traprock.

Table 24.—Crushed traprock sold or used by producers in the United States, by use

(Thousand short tons and thousand dollars)

Use	1974 [r]		1975

[r] Revised.

[1] Includes other fillers, asphalt fillers, building products, poultry grit (1974), waste materials (1974), and other uses.

[2] Data do not add to total shown because of independent rounding.

SANDSTONE

Dimension.—Dimension sandstone was used mainly for building stone. Output of rough building stone increased 18% to 51,500 tons valued at $974,000. Sales of rough blocks increased 12% to 43,600 tons valued at $868,000. Output of rubble increased 6% to 35,300 tons valued at $395,000. Production of cut building stone declined 11% to 25,800 tons valued at $1.75 million. Output of house stone veneer declined 15% to 20,300 tons valued at $705,000. These five uses accounted for 77% of the total output of dimension sandstone.

Table 25.—Dimension sandstone, quartz and quartzite sold or used by producers in the United States, by use

Total [2]	260,940	3,430,700	8,692	229,460	3,007,026	8,001

[r] Revised.

[1] Includes dressed construction stone, rough monumental, other rough stone, curbing, dressed monumental, and other dressed stone.

[2] Data may not add to totals shown because of independent rounding.

Crushed.—Output of dense-graded roadbase stone declined 21% to 6.4 million tons valued at $13.9 million. Production of other aggregates and roadstone declined 10% to 5.59 million tons valued at $12.5 million. Output of bituminous aggregate declined 27% to 2.34 million tons valued at $6.48 million. Production of concrete aggregate increased 2% to 2.18 million tons valued at $6.07 million. Output of riprap declined 27% to 1.81 million tons valued at $3.95 million. These five uses accounted for 68% of the total output of crushed sandstone.

MARBLE

Dimension.—Dimension marble was used mainly for building stone. Sales of rough blocks declined 24% to 25,700 tons valued at $2.49 million. Output of cut building stone declined 44% to 4,850 tons valued at $1.64 million. Production of sawed building stone increased 13% to 1,300 tons valued at $300,000. Of the total production, 51% was sold as rough blocks.

Crushed.—Crushed marble was used mainly as a filler or as whiting. Output of other filler increased 3% to 747,000 tons valued at $11.4 million. Production of terrazzo was 234,000 tons valued at $4.76 million, a decrease of 2%. Of the total output of crushed marble, 51% was used for other filler.

SLATE

Dimension.—Dimension slate was used mainly for flagging, roofing, and flooring. Output of flagging declined 14% to 25,300 tons valued at $1.06 million. Production of structural and sanitary fixtures declined 29% to 11,800 tons valued at $2.42 million. Output of roofing slate declined 20% to 11,000 tons valued at $2.17 million. Output of slate for flooring declined 14% to 6,300 tons valued at $969,000. These four uses accounted for 88% of the total production of dimension slate.

Crushed.—Crushed slate was used for lightweight aggregate (67%), roofing granules, and other uses. Total output declined 45% to 761,000 tons valued at $4.94 million.

SHELL

Output of roadstone was 6.18 million tons valued at $22.1 million, considerably more than in 1974. Shell used in cement declined 39% to 3.72 million tons valued at $10.8 million. Production of roadbase stone declined 50% to 3.49 million tons valued at $11.7 million. Shell used in lime was 993,000 tons valued at $3.12 million, considerably more than in 1974. These four uses accounted for 93% of the total shell output.

CALCAREOUS MARL

Marl was used mainly for cement and soil conditioning. Marl used in cement declined 15% to 2.69 million tons valued at $3.36 million. Output of agricultural marl declined 8% to 486,000 tons valued at $966,000. These two uses accounted for 90% of the total marl output.

MISCELLANEOUS STONE

Dimension.—Miscellaneous dimension stone was used mainly as building stone. Output of rough building stone expanded 76% to 16,200 tons valued at $365,000. Rubble production was 12,000 tons valued at $133,000. Output of cut building stone declined 28% to 3,700 tons valued at $345,000. These three uses accounted for 86% of the total output.

Crushed.—Output of roadbase stone increased 27% to 5.57 million tons valued at $13.5 million. Output of roadstone increased 10% to 2.46 million tons valued at $4.66 million. Production of bituminous aggregates declined 62% to 1.65 million tons valued at $4.52 million. Stone used for fill decreased 5% to 1.28 million tons valued at $2.23 million. Output of riprap declined 34% to 1.21 million tons valued at $1.94. These five uses accounted for 86% of the total production of miscellaneous stone.

PRICES

Values reported to the Bureau of Mines represent the average selling prices f.o.b. mine or plant and do not include transportation away from the plant.

Unit values for dimension stone ranged from $11.09 per ton for rubble to $516.16 per ton for stone used for blackboards, and averaged $70.27 per ton, an increase of 34% over 1974. Values, per cubic foot, were: $2.62 for rough blocks; $5.52 for rough monumental stone; $14.08 for cut building stone; $5.35 for curbing; and $0.98 for rubble.

Unit values for crushed stone ranged from $1.09 per ton for waste material to $16.82 per ton for whiting, and averaged $2.35 per ton, an increase of 18% over 1974. Values for roadbase stone were $2.04 per ton; coarse concrete aggregate, $2.18; roadstone, $2.26; stone used in cement, $1.75; and bituminous aggregate, $2.52 per ton.

Unit values for dimension limestone averaged $43.55 per ton or $3.35 per cubic foot; crushed limestone value averaged $2.13 per ton. Value of dimension granite averaged $89.53 per ton or $8.29 per cubic foot; crushed granite averaged $2.30 per ton. Crushed traprock value averaged $2.46 per ton. Dimension sandstone averaged $34.87 per ton or $2.66 per cubic foot; crushed sandstone, quartz, and quartzite averaged $2.85 per ton. Dimension marble value averaged $190.56 per ton or $18.24 per cubic foot; crushed marble was $15.49 per ton. The average value for dimension slate was $120.34 per ton, and $6.50 per ton for crushed slate. Shell sold for $3.41 per ton, and marl was valued at $1.39 per ton. Miscellaneous stone was valued at $34.44 per ton or $2.74 per cubic foot for dimension stone, and $2.19 per ton for crushed stone.

FOREIGN TRADE

Stone was exported to numerous countries but most went to Canada. Building and monumental stone exports included: Granite valued at $1.8 million, of which 52% went to Canada and 31% to Japan; dolomite valued at $1.5 million, of which 36% went to Venezuela, 32% to Canada, and 23% to Chile; marble valued at $410,000, of which 83% went to Canada; and slate valued at $279,000, of which 94% went to Canada.

Crushed stone exports included 3.4 million tons of limestone and 896,000 tons of other stone. Also, $2.4 million worth of manufactured stone was exported.

Stone was imported from many countries, but most of it came from Canada. Total stone imports were valued at $45.6

Table 33.—U.S. exports of stone

(Thousand short tons and thousand dollars)

Year	Building and monumental stone			Crushed, ground, or broken				Other manufactures of stone (value)
	Dolomite		Other (value)	Limestone		Other		
	Quantity	Value		Quantity	Value	Quantity	Value	
1973	59	652	1,244	2,316	5,400	765	4,819	948
1974	86	1,559	1,920	2,793	7,753	625	4,850	2,077
1975	49	1,464	2,449	3,386	9,993	896	5,843	2,376

million. Building and monumental stone imports included: Marble valued at $15.5 million, granite valued at $8.8 million, and other stone valued at $14.6 million. Ninety-one percent of the dressed marble came from Italy; 65% of the dressed granite came from Italy and 25% from Canada; 54% of the rough granite came from Canada and 31% from the Republic of South Africa; and 91% of the rough limestone came from the Dominican Republic.

Crushed limestone imports, mainly from Canada, were 1.6 million tons valued at $2.4 million. Imports of other crushed stone were 1.4 million tons from Canada valued at $2.8 million.

WORLD REVIEW

Stone was produced in almost every country of the world. The largest quantities are produced near the points of consumption, mainly in the highly industrialized countries. World output of dimension stone in 1975 was estimated at 37 million tons. Europe provided about 75% of the total, Asia 18%, and North America 5%. The dimension stone industry is not expected to expand during the next 25 years.

World output of crushed stone in 1975 was estimated at 5.0 billion tons, of which Europe provided 39%, Asia 26%, and North America 23%. Output is expected to expand at a rate of 4% per year and reach 15 billion tons annually by the year 2000.

Canada.—Output of stone in Canada in 1974 was 94.8 million tons, of which 1.87 million tons (20%) was exported. The stone was used for road metal (41%), concrete aggregate (16%), asphalt aggregate (6%), railroad ballast (4%), and other uses (the remainder). Of the total, 86% was limestone and 9% was granite. The leading producing provinces were Quebec (51%) and Ontario (40%).

France.—Output of dimension stone was about 4 million tons. France ranked second in the world in production of dimension stone, with 11% of the total. Output of crushed stone was about 140 million tons, 3% of the world's output.

Germany, West.—West Germany ranked third in world output of stone with 190 million tons, 5% of the total.

Italy.—Italy has long ranked first in the production of dimension stone. Output was about 8 million tons, 21% of the total world production. Output of crushed stone was about 70 million tons.

Japan.—Japan ranked fourth in stone production with 164 million tons, 4% of the total world production.

United Kingdom.—Output of stone in the United Kingdom was 150 million tons, 4% of the total world output. Among the producing countries, the United Kingdom ranked fifth.

U.S.S.R.—Although stone production figures are not available, output is estimated at 500 million tons, 10% of the total world production. The U.S.S.R. ranks second behind the United States in stone production.

TECHNOLOGY

The stone industry continued to be plagued by environmental restrictions and regulations. The Environmental Protection Agency published guidelines for effluents from mining which called for zero discharge of process-generated effluents.

The Stone chapter from Bulletin 667, Mineral Facts and Problems, reviews current technology in the stone industry.

Sulfur and Pyrites

By John E. Shelton [1]

There was a marked increase in sulfur prices in 1975 compared with those in 1974. The average net shipment value f.o.b. mine/plant for Frasch and recovered elemental sulfur increased by 58% from $28.88 per long ton in 1974 to $45.63 per ton in 1975. There were corresponding increases in both export and import prices. The yearend price for Frasch sulfur was $65 per ton.

Production of sulfur in all forms in 1975 decreased 1.4% below that of 1974. For the eighth consecutive year, sulfur production continued to exceed apparent domestic consumption. Sulfur was produced by 71 companies at 185 operations in 32 States; 10 companies with 47 operations accounted for 78% of the output. Production was concentrated in Texas and Louisiana. Together, these two States accounted for 78% of the total output. Distribution of production was as follows: Frasch sulfur 64%, recovered elemental sulfur 26%, and sulfur contained in other forms 10%.

Shipments of sulfur in all forms to domestic and export markets decreased 11% below those in 1974. Frasch and elemental sulfur accounted for 89% of the total sulfur shipped in 1975. The total value of shipments f.o.b. mine/plant was $459.8 million in 1975 compared with $337.1 million in 1974, an increase of 36%. Eighty-seven percent of the shipments was for domestic consumption, and 13%, for export. Shipments of sulfur in all forms in 1975 were 11% less than the quantity produced. Producers' yearend stocks of Frasch and recovered elemental sulfur were almost 30% greater than those at yearend 1974.

The apparent domestic consumption of sulfur in all forms decreased 2% below that of 1974. Sulfur for domestic consumption was obtained mainly from domestic sources: Frasch 45%, recovered elemental 27%, and sulfur in other forms 10%. The remaining 18% was obtained by imports of Frasch and recovered elemental sulfur.

After 4 years of being a net exporter of sulfur in all forms, the United States was a net importer in 1975. Exports of sulfur in all forms decreased 49% from those of 1974. Imports of sulfur in all forms in 1975 were 12% less than those of 1974.

[1] Hydrogen sulfide and liquid sulfur dioxide.

[2] Less than ½ unit.

[3] Accounted for as Frasch sulfur.

[4] Measured as shipments, plus imports, minus exports.

[5] Reported producers' stocks after inventory adjustments.

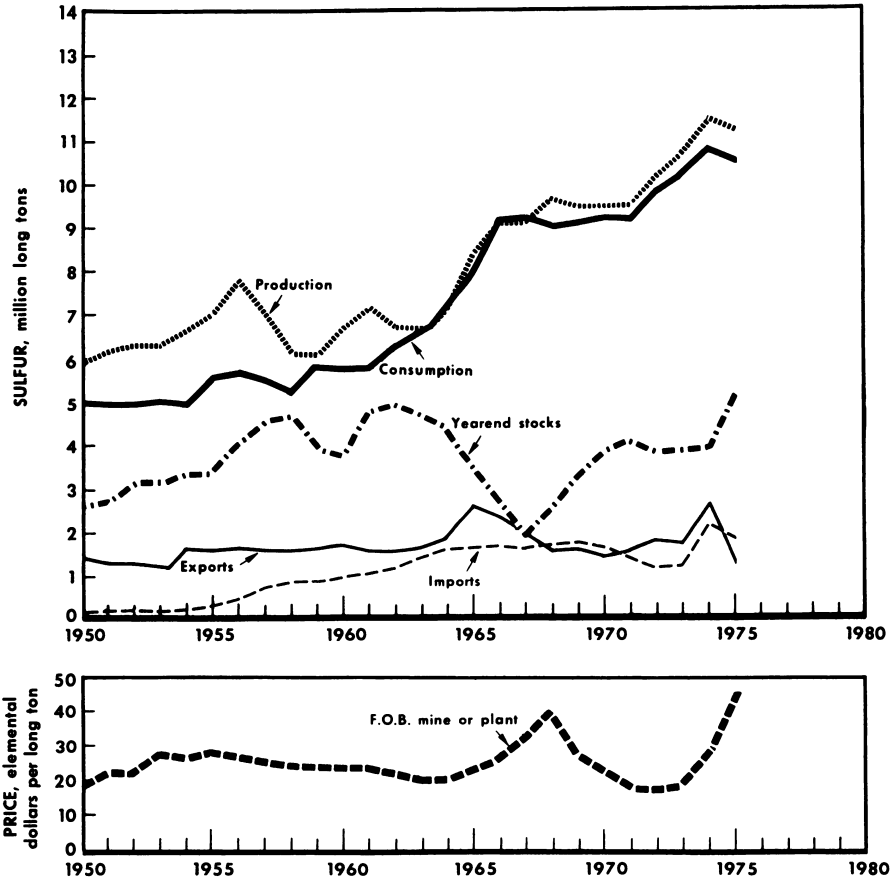

Figure 1.—Trends in the sulfur industry in the United States.

DOMESTIC PRODUCTION

Frasch Sulfur.—Output of Frasch sulfur was 64% of the domestic production of sulfur in all forms in 1975 compared with 69% in 1974.

In 1975, there were 13 Frasch mines, all in Texas and Louisiana. Producers and mines in Louisiana were Freeport Minerals Co. at Garden Island Bay, Grand Isle, Grand Ecaille, and Lake Pelto; and Texasgulf, Inc., at Bully Camp. Producers and mines in Texas were Atlantic Richfield Co. at Fort Stockton; Duval Crop. at Culberson; Jefferson Lake at Long Point Dome; and Texasgulf, Inc., at Boling Dome, Fannett Dome, Moss Bluff Dome, Spindletop Dome, and the new mine at Comanche Creek.

The 11 mines operated by Duval Corp., Freeport Minerals Co., and Texasgulf, Inc., accounted for most of the Frasch sulfur production. A relatively small portion of the output was from the other two producers operating one mine each.

Production was again concentrated at the larger low-cost mines to counteract increasing production costs. The five largest mines, with a production rate in excess of 500,000 tons per year each, accounted for 84% of the total Frasch sulfur production compared with 81% in 1974. These mines also accounted for 54% of the total output of sulfur in all forms in 1975 compared with 56% in 1974. Five mines with production over 100,000 tons accounted for

14% of the total. The remaining 2% of the Frasch output came from the other three mines.

Producers' shipments of Frasch sulfur were 23% less than in 1974. Approximately 21% of the total shipments were for export and 79% were for the domestic market compared with 33% and 67%, respectively, in 1974. Owing to a greater decrease in shipments than in production, producers' reported stocks after inventory adjustments were 30% larger than at yearend 1974.

Despite a decrease in the quantity of Frasch sulfur shipped, the total value of shipments, f.o.b. mine, increased 26% over that of 1974 to an alltime reported high of $305 million. The average unit shipping value, f.o.b. mine, was $50.16 per ton compared with the unit value of $30.52 per ton in 1974, an increase of $19.64 per ton or 64%. The yearend 1975 quoted price for Frasch sulfur was $65 per long ton ex-terminal, Tampa, Fla., an increase of 14% over the quoted price of $57 per ton at yearend 1974.

[2] F.o.b. mine.

Recovered Sulfur.—Production of recovered elemental sulfur, a nondiscretionary byproduct from natural gas and petroleum refinery operations, accounted for 26% of the total domestic production of sulfur in all forms compared with 23% in 1974. Production and shipments reached an alltime high with increases of 13% and 14%, respectively, over those of 1974, indicating the increasing importance of recovered sulfur as a source of domestic supply. This type of sulfur was produced by 56 companies at 140 plants in 28 States, 1 plant in Puerto Rico, and 1 in the Virgin Islands. Most of the plants were of relatively small size, with only five reporting an annual production exceeding 100,000 tons. The 10 largest plants accounted for 42% of the output, and the combined production from the 5 leading States was 67% of the total. By source, 55% was produced by 38 companies at 79 refineries or satellite plants treating refinery gases, and 2 coking operations, and 45% was produced by 29 companies at 59 natural gas treatment plants.

The five largest recovered elemental sulfur producers were Exxon Co., U.S.A., Getty Oil Co., Mobil Oil Corp., Shell Oil Co., and Standard Oil Co. (Indiana). Together, their 35 plants accounted for 53% of recovered elemental sulfur production in 1975.

The total value of shipments of recovered elemental sulfur in 1975 increased 73% to an alltime high of almost $105 million. The average reported shipment value, f.o.b. plant, was $36.14 per ton, compared with $23.79 per ton in 1974, an increase of 52%. There were wide variations in the reported sales prices by plants in different regions of the Nation because of local competitive factors in the regional markets served by recovered sulfur producers, including competition from Canadian sources.

The leading States in production of recovered elemental sulfur were Texas, California, Mississippi, Florida, and Alabama. Together these States contributed 67% of the total 1975 output. Production in 1975 increased compared with 1974 by 71% in Alabama, 44% in Mississippi, and 14% in Florida. The production rate in California was essentially unchanged, but it decreased by 6% in Texas. Recovery of sulfur in Alabama, Florida, and Mississippi was mainly from the treatment of dry sour natural gas and sour natural gas associated with petroleum in deep Jurassic formations. Indications were of further increases in sulfur recovery in future years.

Table 4.—Recovered sulfur produced and shipped in the United States

W Withheld to avoid disclosing individual company confidential data; included with "Other States."
[1] Combined to avoid disclosing individual company confidential data; includes Colorado, Delaware, Missouri, Montana, New York (1975), North Dakota, Oklahoma (1974), Utah, Virginia, Washington, Virgin Islands, and Puerto Rico (1975).
[2] Data may not add to totals shown because of independent rounding.

Byproduct Sulfuric Acid.—Sulfur contained in byproduct sulfuric acid produced at copper, lead, and zinc smelters and roasters during 1975 was 7% of the total domestic production of sulfur in all forms compared with 6% in 1974. The total output and value reached alltime highs in 1975. In 1975, output was 17% higher and total value was 46% higher than in 1974. Byproduct sulfuric acid was produced by 12 companies at 22 plants in 13 States. Twelve acid plants operated in conjunction with copper smelters, and 10 plants were accessories to lead and zinc roasting and smelting operations. The five largest acid plants accounted for 47% of the output, and production in five States was 78% of the total. The five largest producers of byproduct sulfuric acid were American Smelting and Refining Co., Magma Copper Co., Kennecott Copper Corp., Phelps Dodge Corp., and St. Joe Minerals Corp., whose 13 plants produced 68% of the byproduct sulfuric acid in 1975.

Table 6.—Byproduct sulfuric acid[1] (sulfur content) produced in the United States

1975	521	246	767	42,956

[1] Includes acid from foreign materials.
[2] Excludes acid from pyrites concentrates.
[3] Excludes acid made from native sulfur.

Pyrites, Hydrogen Sulfide, and Sulfur Dioxide.—Contained sulfur in pyrites, hydrogen sulfilde, and sulfur dioxide represented 3% of the total production of sulfur in all forms in 1975, compared with 2% in 1974. The total sulfur content in these products was 34% more than that of 1974, and the value of shipments was 17% higher. Pyrites was produced by three companies at three mines in three States; hydrogen sulfide by four companies at five plants in four States; and sulfur dioxide by two companies at two plants in two States. The three largest producers of these products were Cities Service Co. (pyrites, hydrogen sulfide, and sulfur dioxide); Phillips Petroleum Co. (hydrogen sulfide); and Shell Oil Co. (hydrogen sulfide). These companies combined, at one mine and five plants, accounted for 95% of the contained sulfur produced in the form of these products.

Table 7.—Pyrites, hydrogen sulfide, and sulfur dioxide sold or used in the United States, sulfur content

1975	237	75	312	7,097

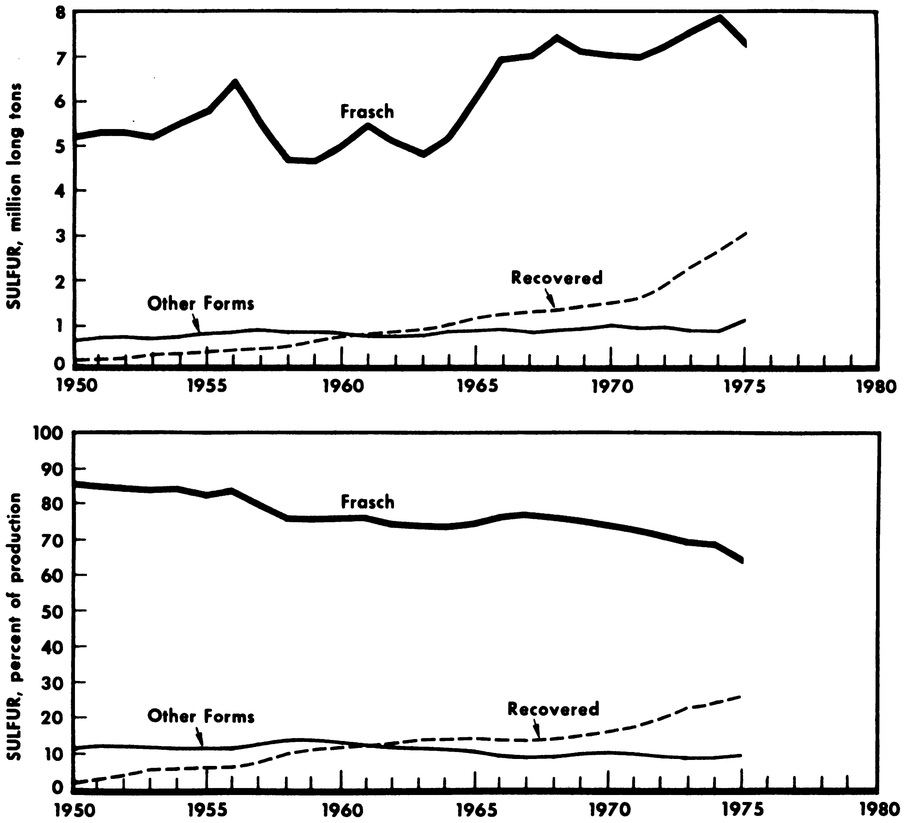

Figure 2.—Trends in the production of sulfur in the United States.

CONSUMPTION

In 1975, apparent domestic consumption of sulfur in all forms was 10.6 million tons, 2% below the alltime high in 1974. Eighty-two percent of this consumption was from domestic sources compared with 80% in 1974. The supply sources were domestic Frasch sulfur, 45% compared with 49% in 1974; domestic recovered elemental sulfur, 27% compared with 23% in 1974; and combined domestic byproduct sulfuric acid, pyrites, hydrogen sulfide, and sulfur dioxide, 10% compared with 8% in 1974. The remaining 18% of the sulfur was from imports of Frasch and recovered elemental sulfur compared with 20% in 1974.

The apparent sales of domestic Frasch sulfur to domestic consumers decreased by 515,000 tons, or 10% below shipments in 1974. Apparent shipments of recovered elemental sulfur for domestic consumption increased by 360,000 tons, or 14% over those in 1974. The reported sales of byproduct sulfuric acid, pyrites, hydrogen sulfide, and sulfur dioxide increased 193,000 tons or 22% above those in 1974. Total supplies of domestic sulfur in all forms to the domestic market increased by 38,000 tons. Total imports of Frasch and recovered elemental sulfur decreased 253,000 tons or 12% below those of 1974. Imports of Frasch sulfur increased 13,000 tons, while imports of recovered elemental sulfur from Canada decreased 264,000 tons and from other countries by almost 2,000 tons.

Approximately 90% of all sulfur consumed was converted to sulfuric acid prior to final end use. The manufacture of fertilizers accounted for about 56% of all domestic sulfur consumption. Plastics, synthetic products, paper products, paints, nonferrous metals production, and explosives accounted for about 21% of domestic demand. The remaining uses were widespread, as most products require sulfur in one form or another during some stage of their manufacture. By region, the distribution of sulfur consumption was as follows: Southern States, except Florida, 42%; Florida, 28%; North-Central States, 11%; Western States, 11%; and Northeastern States, 8%.

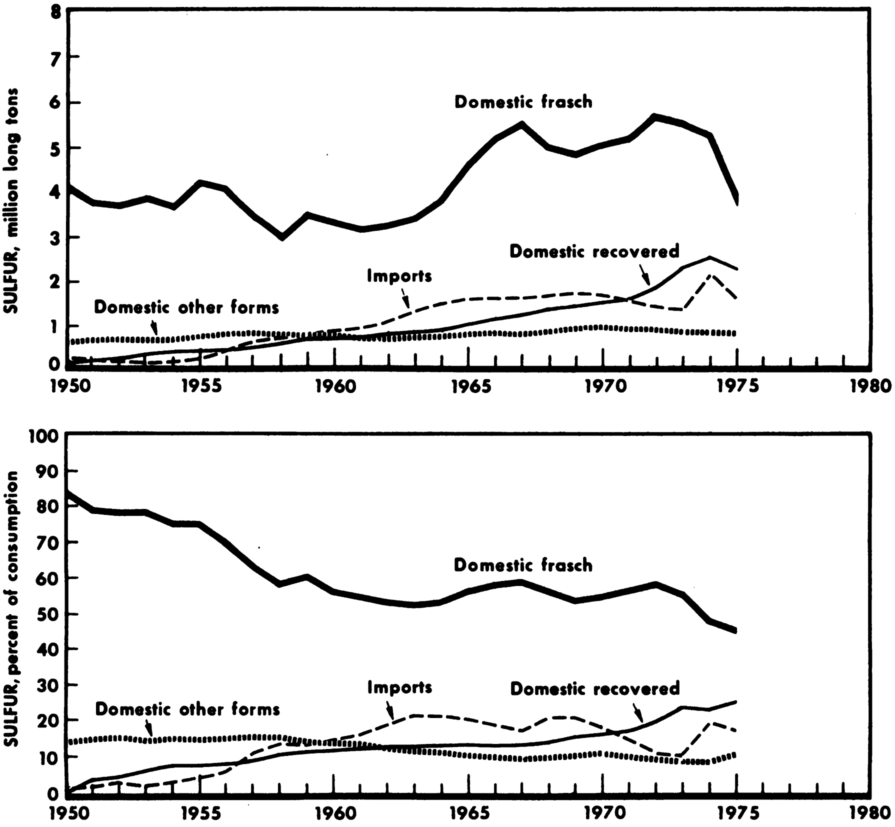

Figure 3.—Trends in consumption of sulfur in the United States.

STOCKS

Producers' stocks of Frasch plus recovered elemental sulfur, after inventory adjustments, increased 30% over the inventory at yearend 1974. Frasch sulfur stocks increased 30% and recovered elemental sulfur stocks increased 26%. The combined yearend stocks amounted to an approximated 6.9-month supply based on 1975 domestic and export demands for domestically produced Frasch and recovered elemental sulfur.

Table 9.—Producers' yearend stocks
(Thousand long tons)

Year	Frasch	Recovered	Total
1971 ------------	4,023	97	4,120
1972 ------------	3,665	131	3,796
1973 ------------	3,816	111	3,927
1974 ------------	3,744	213	3,957
1975 ------------	4,857	269	5,126

PRICES

The quoted price for liquid sulfur ex-terminal Tampa, Fla., rose from $57 per long ton at yearend 1974 to $65 per ton at yearend 1975, an increase of 14%. There were similar price increases in other markets.

On the basis of shipments and total value reported to the Bureau of Mines, the average value of shipments of Frasch sulfur f.o.b. mine for both domestic consumption and exports during 1975 rose to $50.16 per ton, compared with $30.52 per ton in 1974, an increase of 64%.

The recovered elemental sulfur industry was in a less favorable position to obtain full benefit of the higher sulfur prices as this market was subject to regional competitive forces. As a nondiscretionary byproduct there was a general tendency to sell sulfur in local markets. Sales also were more dependent upon the industrial sector of the market. Shipment values varied widely in different regions; lowest in the West, somewhat higher in the midcontinent, and near the values for Frasch sulfur in the East and South. Overall, the reported unit shipment values, f.o.b. plant, in 1975 were $36.14 per ton, up 52% from $23.79 per ton in 1974.

Marketing sulfur produced in other than the elemental form reflected competitive positions in the limited regional markets for these products. In 1975, shipments of sulfur contained in byproduct sulfuric acid increased $11.09 per ton of contained sulfur or 25%, whereas the unit value for sulfur contained in pyrites, hydrogen sulfide, and sulfur dioxide decreased $3.34 or 13% compared with that of 1974.

Table 10.—Reported sales values of shipments of elemental sulfur, f.o.b. mine or plant
(Dollars per long ton)

Year	Frasch	Recovered	Total
1971	17.50	17.37	17.47
1972	17.39	15.60	17.08
1973	18.63	15.45	17.84
1974	30.52	23.79	28.88
1975	50.16	36.14	45.68

FOREIGN TRADE

The United States was a net importer of sulfur in 1975, for the first time since 1970. Imports, in the form of elemental sulfur, decreased 12% to 1.9 million tons. Exports, almost entirely in the form of Frasch sulfur, were down 49% to 1.35 million tons. As a result of the large decrease in exports, the net import balance in 1975 was 545,000 tons compared with a net export of 513,000 tons in 1974.

Exports from the United States were almost entirely in the form of Frasch sulfur. The tonnage of crude sulfur exported in 1975 was 50% less than that in 1974, and exports of refined sulfur declined 67%. The total value of exports declined 26% below that of 1974. The reported average export value was $55.44 per ton in 1975 compared with $37.43 in 1974, an increase of 48%. Belgium-Luxembourg and the Netherlands received 63% of the exports, mainly for transshipment to other European Community Countries. Brazil was the third largest customer, receiving 14% of the exports. Not included in the aforementioned were exports from the Virgin Islands, which were 62,000 tons valued at $1.9 million in 1974 and 57,000 tons valued at almost $3.2 million in 1975.

While imports of sulfur decreased 12%, total value increased 39% and the average value increased 57% from $23.78 per ton in 1974 to $37.35. Imports of sulfur consisted largely of recovered elemental sulfur from Canada and Frasch sulfur from Mexico. In 1975, imports of Frash sulfur from Mexico increased 1%, continuing the penetration of the U.S. market started in 1974, but the value increased 63%. Imports of recovered elemental sulfur mostly from Canada declined 22%, however, the value was up 3%. Despite the overall decrease in imports of sulfur, the total value increased 39%, reflecting higher prices for sulfur in the world market.

WORLD REVIEW

Owing to reduced phosphate fertilizer production and lower usage of sulfur for industrial consumption, demand for sulfur was down. With the weakening of demand, prices for sulfur at yearend 1975 receded from the alltime high in 1974.

World production of sulfur decreased slightly in 1975. Following the pattern of the past several years, production of sulfur in all forms continued to exceed demand. As a result, producers' stocks increased by an estimated 5.5 million tons. Most of the stock increase occurred in Canada where stocks increased 2.5 million tons.[2]

Canada.—Production of sulfur in all forms totaled 7.43 million tons. Recovered elemental sulfur produced at sour natural gas plants, refineries, and tar-sand operations represented 91% of the output. Sulfur contained in byproduct sulfuric acid produced at nonferrous metal smelters accounted for essentially all of the remaining 9% since there was a negligible production of pyrites in 1975.

In 1975, 45 sour-gas plants, 2 in British Columbia, 1 in Saskatchewan, and the remainder in Alberta, were operating with a combined annual capacity of 9 million tons of sulfur. Production from smelter gases was 696,000 tons of contained sulfur in sulfuric acid, an increase of 12% despite reduced base metal output It is expected that smelter gases will continue to increase in importance as a source of sulfuric acid in Canada.[3]

The Province of Alberta accounted for 86% of the Canadian output, with all the production in the form of recovered elemental sulfur. Essentially all production of sulfur was from plants treating sour natural gas and a small fraction was from tar-sand operations. Alberta's production declined 5% to 6.4 million tons in 1975. Shipments of sulfur decreased from 4.9 million tons in 1974 to 3.8 million tons in 1975. Of these shipments, 2.2 million tons was to offshore foreign markets other than the United States, down from 3.0 million tons in 1974. Producers' stocks rose to 16.1 million tons at yearend 1975 from 13.5 million tons at yearend 1974.

The value of marketed sulfur, f.o.b. plant, was $19.24 in December 1975 up from $18.52 in December 1974.[4]

Cyprus.—Production of pyrite and cupreous pyrite was down to 178,000 tons in 1974 from a peak of 1.098 million tons in 1960. According to Sulphur magazine, in 1960 exports of pyrite represented 20% of the total export value of Cyprus but had dropped to 7.5% by 1973 when production was 470,000 tons and exports were 322,000 tons.[5]

France.—Production of sulfuric acid declined about 20% paralleling the decline in demand for sulfuric acid for production of phosphatic fertilizers.[6]

Reserves of sour natural gas near the village of Lacq were estimated at 8,125 million cubic feet with a total recoverable sulfur content estimated at 50 million tons.[7]

Iraq.—The sulfur deposits of the Mishraq area have an estimated resource of

200 million tons of sulfur. The hydrodynamic mining process used at this deposit, results in problems associated with the movement of injected water such as pollution of the River Tigris, loss of heating water, and subsidence. A study of the geohydrology of the area may help to minimize some problems.[8]

Japan.—There were indications that the demand for sulfuric acid was picking up during the last half of 1975. Because of the general downturn in the economy particularly for titanium dioxide and fibers, the demand for sulfur had declined. Production of sulfuric acid was curtailed as stocks reached a postwar high of 199,000 tons in January.

Mexico.—Production of Frasch sulfur decreased from 2.3 million tons in 1974 to 2.1 million tons in 1975. Total exports declined 25% to 1.4 million tons in 1975. This decline in markets was essentially in Western Europe and Asia whereas exports to the United States were essentially unchanged at 1.0 million tons.

Poland.—Total exports of Polish sulfur were slightly higher in 1975 than in 1974. Exports to market economy countries and the U.S.S.R. were about the same, whereas shipments to the rest of the world declined 23% from 1974.

Spain.—According to Sulphur magazine national economic development plans expect production of pyrite to increase from the current annual production of about 2.5 million tons per year to 4 million tons per year by 1980. In addition to production of sulfuric acid and iron cinder, it is expected that copper, lead, zinc, gold, and silver will be recovered as byproducts.[9]

U.S.S.R.—Production of sulfuric acid in the U.S.S.R. increased 12% to 18.3 million tons in 1975. Production of sulfur will be increased at the Orenburg gasfield. Construction of the third phase of the Orenburg complex will be built by the U.S.S.R. with engineering by the French engineering group, Technip, and will utilize technology by Société Nationale des Pétroles d'Aquitaine (SNPA).[10]

e Estimate. p Preliminary. r Revised. NA Not available.

[1] In addition to the countries listed, a number of nations refining oil and processing nonferrous metals may produce sulfur, but such output is regarded as small and is largely, if not entirely, consumed by the producer.

[2] Exports, regarded as virtually equivalent to production, owing to minimal domestic consumption levels.

[3] May also produce sulfur from metallurgical operations and/or natural gas, but output is not reported quantitatively and no reliable basis is available for formulation of output level estimates.

[4] May also produce sulfur from natural gas and/or petroleum, but output is not reported quantitatively and no reliable basis is available for formulation of output level estimates.

[5] Includes a small output from byproduct pyrite.

[6] May also produce sulfur from petroleum refining, but output is not reported quantitatively and no reliable basis is available for formulation of output level estimates.

[7] Less than ½ unit.

[8] May also produce sulfur from metallurgical operations, but output is not reported quantitatively and no reliable basis is available for formulation of output level estimates.

[9] Sulfur content of H_2S gas and liquid SO_2 not included elsewhere.

[1] In addition to the countries listed, Chile produces a small quantity of byproduct pyrite, but data are incomplete to estimate gross pyrite production.

[2] Sold or used by producers.

[3] Exports.

TECHNOLOGY

The hydrodynamic method of sulfur recovery was developed to treat the Polish sulfur deposits, which were widely dispersed, relatively thin bedded, and frequently underlain by pervious strata that were not amenable to successful application of the Frasch process.[11]

Research in the quenching of liquid sulfur to reduce problems of dusting, water retention, and loading, and to facilitate storage and later transport was discussed.[12]

A stack gas cleanup process that removes particulates prior to removal of SO_2 resulted in a discharge containing 44 parts per million sulfur dioxide and 0.004 gram per standard cubic foot particulates. The SO_2 was absorbed by dilute sulfuric acid, was converted to sulfuric acid in the presence of a dissolved ferric sulfate catalyst, and was finally neutralized with limestone. The resulting gypsum is of high enough quality for use in Japan's building industry.[13]

A double alkali wet scrubbing system using sodium and calcium hydroxides has been found effective in removing SO_2 from flue gases.[14]

Chemical Week. Two-step Method to Stack-Gas Cleanup. V. 118, No. 4, Jan. 28, 1976, p. 29.

A molten salt bath of lithium, sodium, potassium, and calcium carbonates has been used to remove sulfur and particulates from low-Btu gas made from coal. The process saves energy in that the gas is passed through the molten bath at 700° C rather than cooling the gas to room temperature for hydrogen sulfide removal and reheating for combustion. The process removed 98% of the sulfur but was only half as efficient in particulate removal and picked up too much of the alkali metals.[15]

The types and construction of tall stacks were discussed.[16] Tall stacks have been built since the early 1800's. A typical chimney for a 1,000-megavolt fossil fuel generating station would be 800 feet tall. The tallest stack in the world is 1,250 feet 9 inches at International Nickel Co.'s Copper Cliff smelter, Sudbury, Ontario.

Sulfur dioxide discharged in the atmosphere may undergo, in addition to and in conjunction with dilution and dispersal, a broad combination of secondary processes. Little is known about the detailed mechanism of the individual processes. Until the nature of these processes and their potential effects can be fully ascertained, tall stacks and sulfur dioxide emission limitation programs at isolated individual sources have been shown to be both appropriate and achievable control measures for attaining and maintaining ambient SO_2 standards.[17]

Coal in the presence of steam was found to act as a reductant to produce elemental sulfur from sulfur dioxide in powerplant, metallurgical, and chemical-processing flue gases. A flue gas of about 20% by volume of SO_2 was treated to produce a marketable liquid sulfur.[18]

A stack cleaner has been developed that removes both solid and gaseous waste simultaneously. Basically, the equipment centers around an impinger, which forces particulates in the gas to agglomerate with droplets of solution into which sulfur oxides were absorbed and drop out. The resulting sludge can be combined with ammonia and phosphate to produce a chemical fertilizer.[19]

A study was completed of the functional relationship between important operating variables and organic sulfur removal from coal. Temperature, pressure, and solvent-to-coal ratio were examined in a statistically designed experiment at three levels, and mathematical models of sulfur form removal as a function of these parameters were constructed. A parameter study was made of sulfur removal from coal utilizing the co-steam reaction in insitu hydrogen. Also, a study showed the overall kinetics of sulfur removal from coal during dissolution.[20]

A review of the use of sulfur in concrete showed that in addition to increased strength, the concrete had greater resistance to corrosion by sulfuric acid, reduced the quantity of steel needed in reinforcement, and increased resistance to both wear and deicing chemicals in bridge surfaces.[21]

A high-strength construction material consisting of asbestos fibers, and silica flour bonded with plasticized sulfur was developed. Potential uses of the material for handling salt and acid solution were as pipe for acid mine wastes, acidic sewer products and corrosive liquids; as linings for vats, tanks, and ditches where control of leach and waste water is essential; and as flooring in industrial operations where salt corrosion is a problem.[22]

The reaction of sulfur trioxide with metal oxides and sulfides may have potential in leaching ores. Metallic components of ores acted as catalysts in the treatment of the ores with SO_2 and oxygen to form metallic sulfates.[23]

Talc, Soapstone and Pyrophyllite

By J. Robert Wells[1] and Robert A. Clifton[2]

The economic recession of 1975 caused such a drop in demand for the various industrial talcs that production was the lowest since 1967, and sales were the lowest since 1968. The sales value was the lowest since 1961.

The Johns-Manville Corp. announced plans to close its Dunn, Calif., plant and to increase the capacity of its Los Angeles plant. Its mine at Warm Springs, Calif., is scheduled for a return to an underground operation in the spring of 1976.

The State of California and the U.S. Congress are eyeing some real limits on mining activities in Death Valley National Monument where several talc mines operate. As proposed, the legislation would impose a moratorium on new claims within the monument, closely examine the legitimacy of all claims issued prior to January 1, 1976, and protect the rights of the present miners at least until the effects of a ban of all mining could be studied.

[1] Excludes powders—talcum (in package), face, and compact.

Legislation and Government Programs.—Defense materials inventories reported by the General Services Administration showed that Government holdings as of December 31, 1975, included 1,149 short tons of talc (steatite, block or lump) purchased in compliance with a stockpile objective, and 2,916 short tons of talc (steatite, ground) acquired in nonstockpile transactions.

The Office of Minerals Exploration, Geological Survey, offered to grant loans of up to 50% of approved exploration costs for eligible deposits of block steatite talc, but no loans for that purpose were made in 1975. The allowable depletion rates for talc, established by the Tax Reform Act of 1969 and unchanged through 1975, were 22% on production of block steatite talc of domestic origin and 14% on foreign production of the same material, which rate applied also to production of all other classes of talc from all sources.

The Federal Register of October 9, 1975, contained the new Office of Safety and Health Administration (OSHA) proposal to go to a 0.5 fiber per cubic centimeter permissible asbestos exposure level. The talc position is still not a clear one, as in the text of the proposal no differentiation is made between fibrous and nonfibrous tremolite and some other amphiboles. The proposal is being fought vigorously by the asbestos industry.

---

[1] Former physical scientist, Division of Nonmetallic Minerals, now retired.
[2] Physical scientist, Division of Nonmetallic Minerals.

Several members of the talc industry were cooperating with a joint Mining Enforcement and Safety Administration (MESA)—National Institute of Occupational Safety and Health (NIOSH) study on the health of talc workers.

DOMESTIC PRODUCTION

Mine production of crude talc and related minerals in the United States in 1975 dropped to a 7-year low and was just 72% of that produced in 1974. The value of these minerals was at a 3-year low and was 87% of 1974 value.

Mines in six States produced 95% of the tonnage and 98% of the value of the talc-group minerals in 1975, and the production in eight other States accounted for the rest. The largest producing States in decreasing order are Vermont, New York, California, Texas, Montana, and North Carolina. Every State, with the exception of Nevada, that produced these minerals had one or more mills to process the ore.

Talc was produced at 30 mines in 7 States in 1975, with California having by far the largest number of active mines at 12. Soapstone was produced in 7 States at 10 mines, 3 of which were in Texas. The six mines producing pyrophyllite in North Carolina no longer give that State a monopoly. The Interpace Corp.'s Victorite mine in California was active in 1975.

Table 2.—Talc, soapstone, and pyrophyllite produced in the United States, by State

State	1974		1975	
	Quantity (short tons)	Value (thousands)	Quantity (short tons)	Value (thousands)

[r] Revised.

[1] Includes Alabama, Arkansas, Maryland (1974), Montana, Nevada, New York, Oregon, Virginia, and Washington.

The 10 largest domestic producers of talc minerals in 1975, listed alphabetically, were as follows: Cyprus Industrial Minerals Co., with mines in California, Montana, and Texas; Eastern Magnesia Talc Co. in Vermont; Johns-Manville Corp. in California; Pfizer Inc., Minerals, Pigments & Metals Div., in California and Montana; Piedmont Minerals Co., Inc., in North Carolina; Southern Clay Products, Inc., in Texas; Standard Minerals Co., Inc., in North Carolina; R. T. Vanderbilt Co., Inc., in New York; and Windsor Minerals, Inc., in Vermont. Those firms supplied 87% of the 1975 tonnage (79% of the total value), and the combined output of about 18 smaller producers made up the remainder.

Talc minerals were ground for sale or industrial use in 1975 at 37 mills operated by 29 companies in 12 States. Talc mined in Nevada was shipped elsewhere for grinding.

W Withheld to avoid disclosing individual company confidential data.

CONSUMPTION AND USES

The apparent domestic consumption of the various talc-group minerals totaled 796,000 tons in 1975, which was 13% below that of 1974 and just 78% of the record high in 1973. Sales of ground material reported for 1975 were only 77% of those in 1974. The total value of these minerals in 1975 was $15 million below that reported for the crude and ground in 1974.

The following percentages of the talc-group minerals used in major amounts by discrete industry segments reflect data reported by producers and do not correlate with table 5 because of differences in the export data and the total caused by that difference. Obviously there is some resale by original purchasers. The ceramic industry is the largest user of these minerals with 22%, paint is next with 17%, paper 8%, refractories 6%, roofing and insecticides at 5% each, toilet preparations 4%, rubber 2%, and asphalt filler 1%.

Table 5.—Talc, soapstone, and pyrophyllite sold or used by producers in the United States, by use
(Short tons)

Use	1974	1975
Asphalt filler	12,186	9,188
Ceramics	221,365	185,138
Exports[1]	182,706	157,681

Rubber	25,128	15,764
Textiles	14,428	3,158
Toilet preparations	34,628	31,241
Other uses[3]	r 187,771	189,345
Total	1,064,085	931,200

r Revised.
[1] Department of Commerce, Bureau of the Census data.
[2] Includes pyrophyllite used for brick manufacture.
[3] Includes art sculpture, crayons, floor tile, foundry facings, plastics, rice polishing, stucco, and other uses, not specified.

Generalizations and/or extrapolations to the broad economic picture are not likely to be valid, but the change in demand for talc-group minerals during a recession provides an interesting picture. Only the refractories industry purchased more in 1975 than in 1974 with an 8% increase. Toilet preparations usage was at 90% of the 1974 level, insecticides and paint at 89%, roofing 86%, ceramics 84%, paper 76%, asphalt filler 75%, rubber 63%, and textiles just 22%.

STOCKS

According to estimates based on data reported by producers, the total quantity of crude, ground, and partly processed talc-group minerals of domestic origin on hand in the United States (that is, mined but not yet sold or used) was approximately 255,000 tons on December 31, 1975, compared with 225,000 tons on that date in 1974.

PRICES

Engineering and Mining Journal, December 1975, quoted prices for domestic talc, ground, in carload lots, f.o.b. mine or mill, containers included, per short ton, as follows:

Vermont:	
98% through 325 mesh, bulk	$27.00
99.99% through 325 mesh, bags:	
Dry processed	70.00
Water beneficiated	100.00
New York:	
96% through 200 mesh	34.00
98% to 99.25% through 325 mesh	$36.00– 48.00
100% through 325 mesh, fluid energy ground	58.00– 95.00
California:	
Standard	69.50
Fractionated	37.00– 71.00
Micronized	62.00–104.00
Cosmetic/steatite	44.00– 65.00
Georgia:	
98% through 200 mesh	20.00
99% through 325 mesh	35.00
100% through 325 mesh, fluid energy ground	85.00

American Paint & Coatings Journal, June 7, 1976, listed the following prices per ton for paint-grade talcs in carload lots:

California:	
325 mesh, bags, mill:	
Fibrous, white, high oil absorption	$34.00–$37.00
Semifibrous, medium oil absorption	32.00– 73.95
Montana:	
Ultrafine grind, f.o.b. mill	70.00
New York:	
Nonfibrous, bags, mill:	
98% through 325 mesh	46.50– 50.50
99.4% through 325 mesh	55.50
Trace retained on 325 mesh	105.00
Fine micron talcs (origin not specified)	68.00–111.50

The price range quoted in Chemical Marketing Reporter, December 29, 1975, for carload lots of imported Canadian talc, ground, in bags, was from $20 to $35 per ton, f.o.b. works.

The approximate equivalents, in dollars per short ton, of the price ranges quoted in Industrial Minerals (London), December 1975, for steatite talc, c.i.f. main European port, were as follows:

Norwegian: Ground (ex store)	$54.00–$59.00
Micronized (ex store)	85.00–134.00
French, fine ground	72.00–169.00
Italian, cosmetic grade	161.00–207.00
Chinese	107.00–132.00

FOREIGN TRADE

Exports.—The general sluggishness of the 1975 talc market was reflected in foreign trade figures. The quantity of talc-group minerals exported from the United States in 1975 was 14% less in tonnage and 6% less in total value than in 1974. The largest share of the exported material went to destinations in Mexico, followed in descending order by Canada, Belgium-Luxembourg, and Venezuela. Shipments to these countries accounted for 89% of the 1975 tonnage and 77% of the corresponding total value; the remainder was distributed among about 50 other countries.

Table 6.—U.S. exports of talc, soapstone, and pyrophyllite, crude and ground
(Thousand short tons and thousand dollars)

Year	Quantity	Value
1973	180	6,618
1974	183	6,711
1975	158	6,338

Imports.—In 1975 U.S. imports for consumption of talc, steatite, or soapstone in unmanufactured form were 23% less in tonnage and 34% less in total value than in 1974. Total value of U.S. imports in the Census Bureau's classification "Talc, steatite, and soapstone and articles of these, not specially provided for" amounted to $198,090, a decrease of 12% from the 1974 figure. As in 1974 the foremost supplier of this class of material (with 47% of the 1975 total) was the People's Republic of China.

Tariffs.—Schedules applicable throughout 1975 were unchanged from those in 1974.

WORLD REVIEW

An article in an industrial journal presented an analysis of the manifold aspects of today's worldwide talc industry. The most prominent producers in several of the major talc producing countries were identified, the locations and geological characteristics of their deposits were described, and some information was reported concerning the beneficiation procedures and production capacities of those organizations. Attention was given in some detail to the talc scene in about 20 individual countries ranging alphabetically from Afghanistan to Zambia. Talc-group consumption patterns in the more industrialized nations were outlined, and a concise summary was included showing the ramifications of the international export-import trade in talc minerals.[3]

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Southern Rhodesia is believed to produce talc, but available information is inadequate to make reliable estimates of output levels.

[2] Calendar year begins March 20 of year stated.

[3] Includes talc and wonderstone (pyrophyllite).

[4] Includes talc and pyrophyllite; in addition, pyrophyllite clay was produced as follows in short tons: 1973—[r] 349,196; 1974—466,030; 1975—377,300.

[5] Data based on Nepalese fiscal year, beginning mid-July of year stated.

TECHNOLOGY

Variations in rare-earth elements distribution in soapstone from different eastern Virginia quarries has led to an unusual method of affirming prehistoric sociopolitical boundaries according to a prominent magazine.[4] The variations, measured by neutron activation analysis enabled tracing of soapstone artifacts to their original quarries and so delineated trading routes and boundaries.

A great deal of research money was being expended by two groups in the continuing controversy over whether or not some or all of the talc minerals with or without a tremolite constituent should be covered by the asbestos regulations of MESA and those of OSHA. At yearend OSHA Field Memo #74–92 was in effect and it stated: "Fibrous, asbestiform minerals such as fibrous tremolite means naturally occurring asbestiform minerals which prior to, or after crushing and processing, contain fibers made up of fibrils," and companies were being cited by OSHA under the asbestos regulations.

An OSHA proposal for changes in the asbestos regulations published October 9, 1975, in the Federal Register,[5] described the three most commonly used asbestos fibers as the fibrous forms of their respective host or matrix minerals. Tremolite, in the same proposal, is simply described as a calcium magnesium silicate. No word denoting fiber is in the description yet it is included among the asbestos minerals. The new proposal is being contested by the minerals industry, particularly the asbestos and talc segments of that industry, along many lines, including mineralogy.

Thorium

By Rebecca P. Smith [1]

Monazite, the principal source of thorium, continued to be recovered as a byproduct at two mines in Florida by Humphreys Mining Co. and Titanium Enterprises. Thorium was extracted from monazite during rare-earth recovery and stored for future use. Thus, production of thorium was in excess of demand. Practically all thorium compounds used by the domestic industry during 1975 came from previous company stocks or imports.

No major developments occurred in the nonenergy uses of thorium, which included mantles for incandescent lamps, hardeners in magnesium alloys, refractories, and electronic and chemical applications.

Because of the decline in energy consumption and delays in starting up the 330-megawatt electric (Mwe) high-temperature gas-cooled reactor (HTGR) near Greeley, Colo., all orders for other HTGR's were cancelled by General Atomic Co. (GA), the manufacturer, or by the power companies. The future prospects for use of thorium in nuclear fuels remained uncertain. However, research continued on development of a thorium-fueled light-water breeder reactor (LWBR) and a gas-cooled fast-breeder reactor (GCFR), which breeds U_{233} from Th_{232}. The large-scale development, either of these reactors or of a modified Canadian-deuterium-uranium (CANDU) reactor under consideration by the Federal Government, could substantially increase the consumption of thorium.

DOMESTIC PRODUCTION

Exploration.—New occurrences of thorium were discovered in 1975 as a result of exploration for other commodities. Thorian uranite and thorogummite were peported in an abandoned serpentine-talc quarry located in Northampton County, Pa.[2] Buttes Gas & Oil Co. began a study of a large deposit of titanium in southwestern Colorado believed to contain a significant amount of thorium. In December, the Energy Research and Development Administration (ERDA) established a regional office in Atlanta, Ga., to evaluate the potential of uranium and thorium resources in the Southeast.

Mine Production.—In 1975, as in the past, thorium was extracted as a byproduct during the recovery of rare-earth elements from monazite, which was separated from beach sands mined for titanium minerals. Humphreys Mining Co. near Hilliard, Fla., and Titanium Enterprises near Green Cove Springs, Fla., were the only domestic producers of thorium. Humphreys Mining Co. trucked wet concentrates from its mine in Florida to its dry plant at Folkston, Ga. U.S. mine production of thorium in 1975 was slightly above the 1974 production.

Refinery Production.—During 1975, only one domestic firm, W. R. Grace & Co., Davison Chemical Div., at Chattanooga, Tenn., had facilities for processing large tonnages of monazite. Although W. R. Grace did not produce any thorium compounds from monazite to sell, thorium was extracted during the refining of rare-earth elements and stored. Virtually all thorium compounds used domestically during 1975 came from company stocks or imports.

Westinghouse Electric Corp	Bloomfield, N.J	Processes compounds and produces metallic thorium.
Do	Columbia, S.C	Nuclear fuels.

CONSUMPTION AND USES

Based on domestic mine production, releases from the Government stockpile, and foreign trade, the estimated apparent domestic consumption of thorium in monazite and thorium compounds for 1975 was 218 short tons of ThO_2 equivalent. However, monazite was processed mainly for its rare-earth content and thorium residues were stored. Actual industrial demand was about 50 tons of ThO_2 equivalent, based mainly on shipments from processors. This is considerably below the 1974 consumption of 80 tons. The decline in consumption during 1975 was mainly due to low demand in energy applications.

Nonenergy uses consumed about 35 tons of ThO_2. The principal application was a constituent in mantles for Welsbach incandescent lamps (estimated to be around 20 tons). Other nonenergy uses were: As a hardener for magnesium-thorium alloys, 4 tons; in refractories, 5 tons; in electronic and chemical applications, plus other applications and research, 6 tons.

The 330-Mwe plant at Fort St. Vrain, Colo., was in the power ascension phase, and operation at 2% power was achieved in May 1975. It is the only licensed HTGR; all other orders for HTGR's were cancelled by GA or by the power companies. In 1975, thorium consumption in energy-related applications was estimated at 15 tons ThO_2. ERDA remained the principal domestic user of thorium. Besides the HTGR-related applications, research continued on the use of thorium in the LWBR, and on the refining and processing of thorium-containing nuclear fuel.

STOCKS

On December 31, 1975, the Government stockpile totaled 7,282,749 pounds of thorium nitrate. The thorium stockpile objective was zero.

Industrial stocks of thorium at the end of 1975 were above previous levels, especially at consuming plants. This was mainly due to a decrease in demand for processing monazite for rare-earth elements. Estimated industrial stocks at yearend as ThO_2 equivalent were monazite, 124 tons, and in compounds and metal, 350 tons.

PRICES

Prices for domestic monazite containing approximately 4% ThO_2 remained stable during the year, and were comparable to 1974 prices. The average declared value of imported monazite from Malaysia and Thailand increased to $207 per short ton from $152 in 1974. The average price per short ton of Australian monazite quoted in Metal Bulletin (London) remained constant during 1975 at $203.

Prices for thorium compounds varied with purity and quantity. An average range of prices was: Nitrate, wire grade 47% ThO^2, $2.95–$3; nitrate, mantle grade, 47% ThO_2, $3–3.10; ThO_2, ceramic grade, 99.9% ThO_2, $6–$12; and ThO_2, nuclear grade, 99% ThO_2, $8–12.

Thorium metal in pellets remained steady at $15 per pound as quoted in the American Metal Market.

FOREIGN TRADE

During 1975, no thorium concentrates or ores were exported. Statistics on other thorium products exported are combined with those of uranium. Although these two elements are not statistically differentiated, it was believed that the amount of thorium exported is minor.

Imports of monazite, mainly for rare-earth content, increased above the 1974 level. As in the past, Malaysia was the principal supplier. In 1975 imports of gas mantles decreased, but imports of thorium compounds, mainly from France, increased.

Table 2.—U.S. foreign trade in thorium and thorium-bearing materials

(Quantity in pounds unless otherwise specified)

e Estimate. r Revised. XX Not applicable.

[1] Includes uranium; thorium and uranium are undifferentiated in official statistics.

[2] Based on manufacture of 1,000 gas mantles per pound ThO_2.

WORLD REVIEW

The predominate source of the world's thorium is monazite, a byproduct of titanium and tin mining. Australia, India, Malaysia, Brazil, and the United States continued to be the leading monazite producers among market-economy countries. The small world demand for thorium however, is not reflected by the quantity of this production, since monazite is processed mainly for its rare-earth-element content.

Table 3.—Monazite concentrates: World production by country

(Short tons)

Country [1]	1973	1974	1975 ^{p}
Australia	4,725	4,206	4,704

[1] In addition to the countries listed, Indonesia and North Korea may produce monazite, but information is inadequate to make reliable estimates of output levels.

[2] Exports.

[3] Revised to zero.

Australia.—According to the Rutile & Zircon Development Association, Ltd., monazite production by member companies in 1975 was, by state, New South Wales, 1,207 short tons; Queensland, 685 short tons; and Western Australia, 3,252 short tons.

Allied Eneabba Pty. Ltd. began production at its heavy mineral sands project. The company mine and wet concentrator were located near Eneabba and a dry separation plant was planned at Meru, the port of export.[3] Reserves were estimated at 220,000 short tons of monazite in the Eneabba minerals field.

Other companies with interest in the Eneabba minerals field of Western Australia included: Jennings Mining Ltd., which was producing heavy minerals; Western Titanium Ltd.; and Western Mining Corp. Ltd., and Mineral Sands Pty. Ltd. which have projects in the area. International Nickel Australia, Ltd., subsidiary of the International Nickel Co. of Canada, Ltd., filed an application to search for monazite and other related heavy minerals in the Eneabba area.[4]

Germany, West.—The 300-Mwe pebble-bed thorium high-temperature reactor (THTR) was under construction at the Hamm-Uentrop station of the power company Vereinigte Elektrizitaetswerke Westfalen AG (VEW). The completion of the THTR developed by Hochtemperatur-Reaktorbau GmbH (HRB) was scheduled for 1977.[5]

According to its studies, HRB concluded that coal gasification by nuclear heat was commercially attractive and technically feasible.[6] It is possible that THTR will be used as the high-temperature reactor for an integrated nuclear process heat-electricity system.

India.—A monazite sand separation plant in Gopalpur in Southern Orissa was under construction by the Government-owned Indian Rare Earths, Ltd. Estimated initial annual production is 4,400 short tons of monazite, which will be a byproduct of ilmenite and rutile mining.[7] This will substantially add to the monazite production of India, which was estimated to be 3,300 short tons in 1975.

India's National Institute of Oceanography conducted an extensive survey of shallow offshore areas for heavy minerals. According to the Institute, India's beaches are rich in heavy mineral placers, containing magnetite, ilmenite, monazite, and garnet.[8]

[7] U.S. Embassy, New Delhi, India. State Department Airgram A-389, Dec. 17, 1975, p. 4.

Liberia.—According to a cooperative study of the U.S. Geological Survey and the Liberian Geological Survey, Liberian coastal sands may contain sufficient monazite and other heavy minerals for profitable extraction. The coastal monazite analyzed 7.2% ThO_2.[9]

South Africa, Republic of.—The proposed major beach sands mining operation north of Richards Bay on the east coast was dependent on completing financial arrangements. The proposed mining area will be approximately 11 miles long by 2 miles wide. Monazite will probably be recovered as a byproduct of the more important economic minerals, rutile and zircon. Final output was expected to be about 75,000 tons of rutile and 150,000 tons of zircon per year.[10]

Sri Lanka.—Work continued at Pulmoddai Beach by the Mineral Sands Corp. of Sri Lanka on installing the infrastructure for a mineral sands plant scheduled to come onstream by 1980.[11] The new complex will have an estimated annual capacity of 500 tons of monazite.

United Kingdom.—Thorium Ltd., a subsidiary of Rio Tinto Zinc, Ltd., Widnes, England, stopped processing monazite as of November 1975.[12] Thorium Ltd. was founded in 1914 to supply the United Kingdom with thorium nitrate for gas mantles.

TECHNOLOGY

Nonenergy research on thorium included studies of metallurgy, separation techniques, abundance, use in geochronology, heat capacity of compounds and metals, superconductivity of its compounds, and reaction of thorium with other elements or compounds.

Experiments on thoria-dispersed magnesium were included as a part of a study involving the processing of materials in near-weightlessness. This is the first part of a 5-year series to be conducted by the National Aeronautics and Space Administration aboard an unmanned rocket.[13]

A summary of data on the thermodynamic properties of thorium and its alloys was reported.[14]

The effect of nitrogen in solid solution on the strength of polycrystalline thorium was the subject of another study. Nitrogen was found to behave similarly to carbon in thorium, as a strong, short-range obstacle to dislocation motion.[15]

A fast and simple technique was developed to separate Th_{227} from the Ac_{227} series.[16]

Another separation technique using adsorption by anion-exchange followed by separation by elution with acid was developed to separate thorium, zirconium, and uranium from silicate rocks.[17]

Several studies have been directed toward the behavior of thorium chlorides in fused chloride salts. One study investigated the reduction of $(Th,U)O_2$ with thorium metal to produce ThO_2 and uranium metal. It may be possible to use this reaction as the first step in the reprocessing of $(Th,U)O_2$ fuel and the separation of uranium for the refabrication of new fuel.[18]

Thorium-related energy research was directed mostly toward reprocessing of thorium fuels, process heat, and the GCFR. Since the cancellation of HTGR orders, research has been reduced, but is likely to revive because of the reactor's possible use in nuclear process heat plants.

ERDA was considering recommending the construction of an integrated HTGR reprocessing and fabricating demonstration plant. Much of the conceptual engineering work was completed. The demonstration plant was scheduled to have a capacity for handling 2,500 fuel elements per year, and could be expanded to a capability of about 10,000 fuel elements per year.[19]

Allied Chemical Corp. continued research on developing a process for recovering uranium and thorium from Fort St. Vrain fuel. The process involved primary burning of the graphite, separation of the particles by a gas classifier, particle breaking by gas jets, secondary burning, and then final separation and processing.[20]

Experiments to verify theoretical physics calculations for a GCFR nuclear power system were underway by GA, ERDA, and the Argonne National Laboratory. The GCFR utilizes the coolant and nonnuclear component technology of the conventional HTGR. GA expects the GCFR to produce nearly 40% more fuel than it consumes. In the breeder, "fertile" uranium and thorium will be transmuted into fissionable materials. The fissionable material, U_{233}, can be used to fuel the HTGR.

Tin

By Keith L. Harris [1]

A world recession caused decreased demand for tin, forcing the International Tin Council (ITC) to place export controls on member producing nations to keep tin prices above the ITC established floor price. World mine production declined 4% from the 1974 level to 225,195 metric tons.[2] The buffer stock increased from 142 tons at yearend 1974 to 20,071 tons at yearend 1975. Tin prices on world markets declined substantially from the record levels attained the previous year.

U.S. consumption of primary and secondary tin decreased 15% to 55,800 tons. The major uses for tin were in tinplate, 34%; solder, 27%; bronze and brass, 14%; chemicals including tin oxide, 7%; and babbitt, 5%. Most of the nation's tin, in the form of slabs, bar, and ingots, came from Malaysia and Thailand. Less than 100 tons of tin came from mines in Alaska, Colorado, and New Mexico. About one-fifth of the tin used in the United States in 1975 was reclaimed from scrap.

W Withheld to avoid disclosing individual company confidential data.
[1] Apparent consumption from 1910 to 1936, inclusive.
[2] Source: Metals Week.
[3] Prior to 1925, world mine production figures are obtained from U.S.B.M. Economic Paper 13.

The only primary tin smelter-refinery operating in the United States in 1975 was the Texas City, Tex., facility of Gulf Chemical & Metallurgical Co. (GCMC). The major feed to the smelter was tin concentrate from Bolivia's State-owned Corporation Minera de Bolivia (COMIBOL).

In January, the ITC reacted to increased production costs by raising the floor and ceiling prices for tin by 6% and 5%, respectively. The average New York price for prompt delivery of Straits (Malaysian) tin in 1975 was 339.82 cents per pound, a significant decrease from the 1974 average of 396.27 cents per pound.

Legislation and Government Programs.—The General Services Administration (GSA) continued commercial sales of tin during the year but at a much lower level than during the previous 2 years. Sales for the year, all commercial, totaled 584 tons while shipments totaled 443 tons. At yearend there was an excess of 169,043 tons above the 41,150 ton objective, of which 6,347 tons was authorized for sale by Congress.

The Office of Minerals Exploration (OME), U.S. Geological Survey, continued its program of offering participatory loans for tin exploration up to 75% of approved costs. No contracts were let during the year.

The depletion allowance for tin remained at 22% for domestic deposits and 14% for foreign deposits.

DOMESTIC PRODUCTION

PRIMARY TIN

Mine Production.—Domestic production of tin in 1975 was less than 100 tons. Most of the year's output came from Colorado as a byproduct of molybdenum mining. Some tin concentrate was produced as a byproduct of gold dredging operations in Alaska and placer operations in New Mexico.

Smelter Production.—The only smelter in the United States is the Texas City, Tex., facility of GCMC. In 1975, GCMC received 6,415 tons of tin in concentrate from Bolivia which formed the base load, together with domestic tin concentrate and secondary tin-bearing materials. Tin production was estimated at 6,500 tons. GCMC continued to operate under a 10-year contract negotiated in 1973 with Bolivia under which Bolivia guaranteed to deliver 6,000 tons of tin in concentrate to GCMC in each of the first 3 years of the contract.

SECONDARY TIN

The United States is the world's largest producer of recycled, or secondary, tin. Secondary tin furnishes about 25% of the total U.S. supply each year. In 1975, secondary tin production declined 17% from the previous year's level to 15,856 tons. Of the tin recycled in 1975, 88% was an alloy constituent of reclaimed bronzes, brasses, solders, and bearing and type metals, or an element in chemical compounds. Only 12% of the recycled tin, mostly from new tinplate scrap, was reclaimed as metal. This latter volume provided only 3% of the total tin supplied to U.S. consumers in 1975, a proportion which does not vary appreciably from year to year.

Proler International Corp. started a new detinning plant at El Paso, Tex. The plant will reclaim about 300 tons of electrolytic tin annually from 100,000 tons of tinplate scrap. Proler also purchased two detinning plants from Vulcan Materials Co., one in Los Angeles and the other in Houston. The Los Angeles plant continued in operation while being modified to increase capacity and improve efficiency but the Houston plant was dismantled and will be modified and enlarged for re-erection at Copperton, Utah.

Metal Cleaning & Processing Inc., a subsidiary of Continental Can Co., began detinning operations at its Wilmington, Del., plant during the year. Unburned cans from municipal waste made up the majority of the plant feed.

Table 3.—Tin recovered from scrap processed in the United States, by form of recovery

(Metric tons)

Form of recovery	1974	1975
Tin metal:		
At detinning plants	1,805	1,689
At other plants	216	228

[r] Revsied. XX Not applicable.

[1] Brass-mill stocks include home scrap, and purchased-scrap consumption is assumed equal to receipts; therefore, lines and total in brass-mill section do not balance.

[2] Omits "machine-shop scrap."

[3] Negative receipts indicate shipments greater than receipts.

CONSUMPTION

Tin consumption was at its lowest level since 1934. Primary and secondary consumption declined 17% and 9%, respectively, with total consumption of tin down 15% or 9,980 tons from that of 1974. Tin consumed in all end uses except white metal declined. The largest decreases were recorded in the consumption of tin in tinplate, down 3,817 tons; bronze and brass, 1,953 tons; and chemicals including tin oxide, 944 tons. Increased use of tin in the white metal category (including pewter, britannia metal, and jeweler's metal) was attributed to the manufacture of items for the United States bicentennial. U.S. brass mills consumed 481 tons of primary tin and 244 tons of secondary tin compared with the 1974 levels of 1,029 tons and 280 tons, respectively.

Table 7.—Consumption of primary and secondary tin in the United States

[1] Includes secondary pig tin and tin acquired in chemicals.

[2] Includes pewter, britannia metal, and jeweler's metal.

STOCKS

Yearend stocks of plant-held pig tin declined 19% from the corresponding period of 1974. Tinplate mills held 68% of the plant pig tin stocks at yearend. Plant stocks were highest in January at 9,967 tons but trended downward, ending the year at 7,407 tons. All stock sectors, except tin in process and jobber-importer stocks declined from the 1974 levels.

PRICES

The world-wide recession had a marked effect on tin prices. Decreased demand caused tin prices to dip into the lower sector of the ITC price range every month of the year. ITC buffer stock purchases supporting the market price were evident in at least 9 months of the year.

Average prices for the year declined substantially from the 1974 record levels. The average price for cash tin on the London Metal Exchange (LME) was £3090.82 per metric ton (311.49 cents per pound) compared with £3493.61 per metric ton (352.08 cents per pound) in 1974. The average Penang price for ex-works Straits tin was M$963.79 per picul[3] (300.99 cents per pound) compared with M$1,136.63 per picul (354.97 cents per pound) in 1974.

The Penang price for ex-works Straits tin began the year at M$910 per picul (284 cents per pound) and rose quickly to the year high of M$1,050 per picul (328 cents per pound) late in January. After the January 31 upward revision of the ITC price range, profit-taking actions caused the price to drop into the lower sector by mid-February, where it remained untll mid-July. Technical factors such as the strength of the U.S. dollar, weakness of sterling, and strong grain markets caused Penang prices to rise into the middle sector of the ITC price range through September. Lack of strong physical demand resulted in the continued decline in the Penang price for the remainder of the year. The yearend Penang price was M$959 per picul (299 cents per pound).

---

[3] One Malaysian dollar (M$) = US$0.4164; 1 picul = 133.33 pounds.

FOREIGN TRADE

Exports of tin metal from the United States declined 58% from the abnormally high 1974 level.

U.S. imports of tin metal increased 10% as the tin supplied by GSA sales declined and consumers returned to foreign supply sources. Of the 44,366 tons of tin metal imported, Malaysia supplied 54%; Thailand, 17%; the People's Republic of China, 14%; and Indonesia, 10%. Imports of tin-in-concentrate, all from Bolivia and destined for the Texas City smelter, totaled 6,415 tons, up 7% over the 1974 level.

Small tonnages of secondary tin enter the United States as alloy constituents in recyclable solders or other alloys, or as tinplate or other scrap, dross, skimmings, and residues. These imports are reflected in consumption figures and account for the differences normally encountered between U.S. production and consumption of secondary tin. Imports and exports of tin in alloy such as babbit, solder, type metal, and bronze are shown in the Minerals Yearbook chapters on copper and lead. Ferrous scrap exports, including those of tinplate and terneplate scrap, are not classified separately.

WORLD REVIEW

INTERNATIONAL TIN AGREEMENT

Tin prices rose from the lowest sector to the ceiling of the ITC price range in the 3 weeks prior to the January 28 meeting of the ITC, allowing the producer nations to initiate an increase in the price range. The range was revised as follows:

	Previous range		Revised range	
	M$/picul	U.S. equivalent cents/pound	M$/picul	U.S. equivalent cents/pound
Floor price	850	265	900	281
Lower sector	850–940	265–294	900–980	281–306
Middle sector	940–1,010	294–315	980–1,040	306–325
Upper sector	1,010–1,050	315–328	1,040–1,100	325–344
Ceiling price	1,050	328	1,100	344

By the April meeting, tin prices had been in the lower sector of the price range for 2 months. The buffer stock had increased from 142 tons to over 5,000 tons. After reviewing market conditions, the ITC placed export controls on member producing nations starting April 18, amounting to about a 17% cutback from production levels of the corresponding period of 1974. Low demand continued forcing the ITC to maintain export controls for the remainder of the year. By December 31 the buffer stock held 20,071 tons.

Negotiations of the Fifth International Tin Agreement (ITA) to come into effect July 1, 1976, were completed during the year. The only substantial changes from the Fourth ITA were as follows: (1) The provision for the buffer stock to be enlarged from 20,000 tons to 40,000 tons through voluntary consumer nation contributions; (2) the provision for the renegotiation of the agreement after 30 months if consumer nation contributions to the buffer stock are not up to adequate levels; and (3) contributions to the buffer stock would be based on the then current floor price rather than the floor price at the beginning of the agreement.

On September 1, the United States announced its intent to join the Fifth ITA.

e Estimate. p Preliminary. r Revised.

[1] Data derived in part from the Statistical Bulletin of the International Tin Council, London, England.

[2] Estimate by the International Tin Council.

[3] Smelter output from domestic ores was as follows in metric tons: 1973-292; 1974-400; 1975-457.

[4] Includes tin content of alloys made directly from ores.

[5] Tin content of production from Metabol and Pero smelters plus exports by ENAF smelter.

[6] Includes small production of tin from smelter in Singapore.

Australia.—Australia's tin production continued to decline for the third consecutive year, reaching 9,678 tons, the lowest level since 1970. All tin production came from four States, with Tasmania the largest producer, followed by New South Wales, Queensland, and Western Australia.

Renison Ltd., Australia's largest tin producer, recorded a slight decline in production for the fiscal year ended June 30. The company treated 452,408 tons of ore at an average grade of 1.25%, recovering 3,889 tons of tin-in-concentrate. During the last half of 1975, export restrictions caused cuts of 25% and 29%, respectively, in concentrate production and sales. The heavy-media separation plant was closed in December until the market situation improved. The joint venture between Renison, the Aberfoyle group, and Consolidated Gold Fields, Australia, Ltd., started diamond drilling at the Mount Lindsay prospect near Renison in Tasmania.

Diamond drilling was suspended at the Gillian prospect near Mount Garnet in northeast Queensland while metallurgical research was carried out. The joint venture between Renison and Otter Exploration, Ltd., has delineated significant areas containing 0.7% tin but treatment may be difficult.

Aberfoyle Ltd., Ardlethan Tin N.L., and Cleveland Tin N.L., all of the Aberfoyle group, produced 185 tons, 1,311 tons, and 1,370 tons, respectively, all at least 10% below the respective 1974 levels, as ITC controls forced cutbacks to 60% capacity. Operations were reduced to 5 days per week. Cleveland Tin's indicated ore reserves as of October 1 were 1.9 million tons grading 0.82% tin and 0.32% copper. Ardlethan Tin reserves on the same date were 2 million tons grading 0.56% tin.

Greenbushes Tin N.L. received permission to divert a highway through the center of its operations, thus providing an additional 5 years of reserves. Greenbushes also obtained a 3-year license to mine Vultan Minerals Ltd.'s neighboring leases. Vultan and Greenbushes leases covered the largest tinfield in Western Australia.

Bolivia.—Tin production, at 28,744 tons, was only slightly below the 1974 level. COMIBOL produced 20,965 tons, 6% above that of 1974. However, the medium and small miners' production, at 6,056 and 1,723 tons, respectively, declined 5% and 46% from the 1974 levels. Total tin exports were down 9% from 1974 levels to 26,440 tons but Empresa Nacional de Fundiciones (ENAF), the national smelting company, increased metal exports from 7,049 tons in 1974 to 7,497 tons in 1975.

The declining ratio of concentrate exports to metal exports will continue as expansion of Bolivia's smelting capacity progresses. The Vinto smelter capacity reached 11,000 tons per year late in 1975. One more plant expansion, to a total capacity of 20,000 tons per year, was projected to be completed by late 1978.

A low-grade smelter will be built near the Vinto complex and was scheduled to start up in 1978 with an initial capacity of 5,000 tons per year, reaching 12,500 tons by 1980. The smelter, featuring three vacuum distillation plants, will be built by Klöckner Industrieanlagen AG and Paul Bergse & Son A/S. Part of the feed for the lowgrade smelter will be supplied by the Soviet-built 400-ton-per-year tin volatilization plant under construction at Potosí. Two more tin volatilization plants were planned for the Machacamarca area. A $1.75 million, 1,500 ton-per-day preconcentration plant started up at Pailaviri as part of the metallurgical complex to feed the low-grade smelter.

The Huanuni mine tin ore processing capacity has increased from 1,080 to 1,200 tons per day with the opening of a new crushing plant.

Bolivian mining costs were reported to be between $3.00 to $3.20 per pound at yearend.

Brazil.—The Brazilian Government approved a $5.3 billion nonferrous metals development program striving to make Brazil self-sufficient by 1983. Domestic production of tin in 1988 was projected at 21,000 tons. The government planned liberal credit extensions to private industry to facilitate the expansion.

An airborne geophysical survey covering 350,000 square kilometers of central Brazil began in midyear. Tin and other nonferrous metals were the subject to the $8 million survey. Promising areas will be made available to private companies for mining.

Bera do Brasil S.A. will close most of its 340-ton-per-year tin smelter in São Paulo because it cannot meet the stringent pollution requirements of the area. The smelting of tin, lead, and their alloys will be moved to a new location outside São Paulo.

Indonesia.—The expansion of the Mentok tin smelter was completed with the addition of three reverberatory furnaces. The capacity was increased from 18,000 to 33,000 tons. Exports of tin concentrate to Malaysia will cease after February 1976 and Indonesia's total tin output will be smelted in the country.

Several offshore discoveries were reported during the year. After 7 years of exploration in its two offshore concessions, N.V. Billiton Maatschappij announced the discovery of a deposit in the area of Pulau Tudju containing "tens of thousands" of tons of tin ore. Billiton planned to begin dredging the deposits in 1978 at the rate of 2,430 tons per year of 70% tin ore.

A 5-year survey by P.N. Timah and Fugro-Cesco BV of a 33,000-square-kilometer offshore area has located a 50-square-kilometer area of new tin reserves near the Riau Archipelago. No reserve figure was made public but the deposit thickness average 20 meters.

The first stage of development of the Kelapa Kampit lode mine on Bilitung Island was completed by P.T. Broken Hill Pty. Indonesia (BHP). The mine was dewatered to the 135-meter fourth level. Most of the shaft timbers were well preserved. First production from the HS2 shaft was expected early in 1976. Two separate workings, one an old Netherlands working and the other a BHP discovery, provided about 100 tons of ore for processing at the pilot mill. Delineation of the ore bodies and determination of production costs were prerequisites to determining if Kelapa Kampit reaches actual production.

Malaysia.—Although tin production declined to its lowest level in 11 years because of export controls, Malaysia continued to lead the world in the production, smelting, and exports of tin in 1975. A total of 64,364 tons of tin was mined, 6% below the 1974 level. At yearend there were 55 tin dredges, 810 gravel pump mines, and 45 opencast, underground, and other miscellaneous mines in operation, reflecting an 11% decrease in total active mines from yearend 1974 levels. Gravel pump operations accounted for 55% of the concentrate produced; dredging, 32%; opencast mining, 4%; underground mining, 3%; and miscellaneous sources, 6%. The tin mining labor force declined 10% to 39,736 workers at yearend.

Metal production, at 83,070 tons was 2% below the 1974 level. Exports of metal decreased to 77,635 tons from 85,229 tons in 1974. Imports of tin in concentrate totaled 18,358 tons, up 35% from those of 1974, but were expected to fall in 1976 after Indonesia ceases to export tin concentrate.

Industry officials continued to warn of problems that reduced prospecting activity to a standstill and created a poor investment climate. Heavy taxation was a substantial deterrent. The tin industry, the heaviest taxed industry in Malaysia, paid export duties, export surcharges, and tin profits, development, and income taxes. Also, delays in processing applications for mining leases and the possible rejection of lease renewal applications have been major contributors to declining production over the past 3 years. Streamlining the application process and reduced taxation have been recommended.

The Geological Survey of Malaysia, in a study of Malaysia's mineral resources, recommended special tax incentives to encourage the exploration of tin lodes. "If the mining industry is to maintain its present important position in the national economy, top priority must be given to the study of tin lodes. This is necessary in view of the fact that the known alluvial tin fields are suffering gradual depletion and it is unlikely that any large new ones will be found to replace them," the report stated.

Export controls and low prices caused closure of 94 gravel pump mines between the end of April and the end of December. A hardship quota pool was established by the Malaysian Government to assist marginal miners in meeting operating costs during the period of export restrictions. Additional production was allowed to qualifying mines to permit production at levels matching operating costs. The pool was not intended to assist mines to operate at a level better than survival level or to give assistance to mines suffering economic hardship caused by factors other than production controls.

Through various complicated stock transactions, Perbadanan Nasional Bhd.'s (Pernas) subsidiary, Pernas Securities (the Malaysian Government investment branch) and Haw Par Brothers International (HPBI) made an effort to obtain majority ownership of London Tin Corp. Ltd. (LTC), the world's largest tin investment group and the largest holder of Malaysian tin mines. The London Takeover Panel required HPBI and Pernas to make a full-scale bid for the remaining 49.7% of the LTC shares not already under their control. HPBI financial problems precluded finalization of the deal and Pernas was seeking another method to attain control in LTC, furthering the Malaysian Government's goal of 70%-domestic private ownership in the tin industry by 1990.

LTC's Malaysian mine holdings consist of Austral Amalgamated Tin Bhd., 14.4%; Berjuntai Tin Dredging Bhd., 37.4%; Kampong Lanjut Tin Dredging Bhd., 34.8%; Kamunting Tin Dredging Ltd., 23.8%; Kramat Tin Dredging Bhd., 30.9%; Kuala Kampar Tin Fields Bhd., 29.3%; Lower Perak Tin Dredging Bhd., 43.2%; Malayan Tin Dredging, Ltd., 39.2%; Southern Kinta Consolidated, Ltd., 31.8%; and Southern Malayan Tin Dredging Ltd., 11.4%. During the fiscal year ended March 31, 1976, total tin concentrate production (including output of companies in Thailand) totaled 16,749 tons compared with 19,806 tons in the previous year. At yearend, the Malaysian companies operated 30 bucket dredges. Two Malaysian based dredges, one owned by Kampong Lanjut and the other by Southern Kinta, were shut down during the year after exhausting the ore reserves. In addition to the dredge closures, reduction in the grade of deposits from about 0.15 kilogram per cubic meter to 0.12 kilogram per cubic meter was a factor in reduced production. Export controls had only a minimal effect on Malaysian mining operations, causing several dredges to reduce operating hours.

Berjuntai Tin Dredging Bhd. continued to be Malaysia's largest tin producing company although output decreased 14% from that of 1974 to 3,893 tons in 1975. The company operates a seven-dredge fleet but the two newest dredges, No. 6 commissioned in 1965 and No. 7 commissioned in 1971, produced more than half the total output. Construction continued satisfactorily on Berjuntai's $7 million No. 8 dredge. The 459,000-cubic-meter-per-month dredge, equipped with 0.6-cubic-meter buckets, will replace Berjuntai's No. 1 dredge when it begins operation July 1976.

Kuala Kampar Tin Fields Bhd., which operates two dredges in the Kinta district of Perak, entered into an option agreement with Boustead Ltd. for the purchase of 113 hectares of tin-bearing land at Trong. Perak. Ore reserves were estimated at 24 million cubic meters containing 0.16 kilogram per cubic meter recoverable tin concentrate.

The pontoon for the first dredge of Selangor State Development Corp's mining subsidiary, Syarikat Timnah Langat Sdn. Bhd., was launched early in 1975. The dredge will be the first of at least three to work the Ulu Langat district. The dredge was expected to be in operation in 1977, working a 690-hectare area in Dengkil and producing about 60 tons of tin ore per month. The Ulu Langat district was expected to become one of the largest tin mining areas in Selangor in the future.

Charter Consolidated Ltd., whose Malaysian tin holdings include a 39.2% interest in Bidor Malaya Tin Bhd., a 29.7% interest in Tronoh Mines Ltd., a 16.4% interest in Ayer Hitam Tin Dredging Ltd., and a 6.3% interest in Sungei Besi Mines Ltd., announced a feasibility study covering an area of deep tinbearing deposits in southern Selangor. Charter (36%), Tronoh (9%), and the Selangor State Development Corp. (55%) had a joint venture agreement on the area. Studies in the design of dredges and stripping equipment to work the reserves were commenced after prospecting and evaluation of the area during the year.

Although Pacific Tin Consolidated Corp., the only U.S. company mining tin in Malaysia, increased tin output in 1975 by 4% over that of 1974, operating revenues declined 9% as the price received per kilogram of tin declined from $7.63 to $6.66.

Bethlehem Steel Corp. has withdrawn from Conzinc Riotinto Malaysia, a joint tin mining venture in which Bethlehem held a 45% interest. The company operated a dredge at Labohan Dagang, Selangor.

Nigeria.—Tin production continued to decline for the seventh consecutive year to 4,652 tons in 1975, the lowest level since 1933. Increased mining costs, including fuel, power, and labor, continued to plague the Nigerian tin industry.

Amalgamated Tin Mines of Nigeria (Holdings) Ltd. (ATMN), Nigeria's largest tin mining company, received the first of two bucket wheel excavators during the year. Successful field trials at ATMN's Sabon Gida tinfield were reported. Because of Nigeria's port congestion, the second excavator and a 2.7-kilometer conveyor system were not shipped until October. Both excavators will work 50-meter-deep tin deposits in the Sabon Gida area. The excavators will be used in conjunction with draglines to strip the overburden and send it by conveyor for dumping in old mine workings about a kilometer away. The system was expected to be operational in mid-1976.

South Africa, Republic of.—The two major South African producers, Rooiberg Minerals Development Co. Ltd. and Union Tin Mines Ltd., increased tin concentrate output during 1975 to 3,686 tons (2,933 tons in 1974) and 1,593 tons (1,217 tons), respectively. The average grade of Rooiberg's gravity concentrates decreased from 63.94% to 63.43%, and flotation concentrates decreased from 28.11% to 24.10% for the year ended June 1975. The Vellefontein mine was opened with the sinking of a new inclined shaft.

Union Tin's increase in production was accompanied by sharply higher operating costs. Ore reserves were limited with little probability of additional discoveries. The tailings dump, where retreatment supplied the majority of Union Tin's production, was rapidly decreasing. Highgrading the mine and decreased exploration were expected to optimize profits during the remaining 2-year life of the mine.

Thailand.—Developing the mining sector as a means of promoting economic growth was made one of the objectives of Thailand's 1972–76 5-year plan. Prior to 1975, the Thai Government liberalized its attitudes towards foreign investment in mining and the duration and size of concessions. In 1975, the investment situation changed.

On March 17, after about 4 months of rising public pressure, the Thai Government withdrew the mining concessions of Thailand Exploration and Mining Co., Ltd. (Temco), the Union Carbide Corp. (46%), N.V. Billiton Maatschappij (46%), and Thai Government (8%) joint venture, charging that Temco had failed to comply with Government regulations. Temco was responsible for 9% of Thailand's 1974 output. Later in the year, the Thai Government failed to renew five of seven mining leases of Southern Kinta Consolidated Ltd. Both of these companies had planned additional investments in offshore tin mining. Temco had considered adding a $20 million dredge to its fleet and Southern Kinta was to add an additional dredge and other investments totaling $28 million. These plans were cancelled.

Thailand's onshore tin reserves continue to be depleted as reflected in Thailand's declining tin production over the past 3 years. To maintain its production levels, offshore deposits must be exploited.

By yearend, some problems had been resolved. Union Carbide had sold its share in Temco to Billiton. A new Government mining body, the Offshore Mining Organization, had agreed to contract with the newly Thai-registered Billiton company, Billiton Thailand Co., to mine Tempco's former concessions.

Illegal mining of offshore areas became a problem of visible proportion for the Thai Government in 1975. It appeared that Thai tin concentrates were being claimed to be of Burmese origin. An indication of the magnitude of the problem was that Malaysia imported 4,942 tons of tin-in-concentrate from Burma in 1975 compared with 528 tons in 1974. Burma's production for 1975, at 600 tons, was the same as in 1974.

Pacific Tin Consolidated Corp., which holds a 49% interest in Sierra Mining Co., Ltd., announced completion of a feasibility study at Sierra's tin dredging property near Sichon in southern Thailand. The study indicated that dredging would be profitable but mining would not commence until Government approval of certain leases. Two dredges were being considered to mine the property, one from a wholly-owned subsidiary of Pacific Tin in California, the other, Pacific Tin's No. 5 dredge in the Ampang area of Malaysia, which has been shut down since early 1975 after exhaustion of reserves.

United Kingdom.—Despite lower ore grades and recovery difficulties, there were moderate increases in mine production for 1975. Increased costs and low tin prices caused several mines to operate at a loss. Despite these financial problems, the mining companies continued development.

The Mount Wellington mine of Cornwall Tin & Mining Corp. continued development with an anticipated production date of early 1976. The mill will have a 200,000-ton-per-year concentrator that will recover about 1,600 tons of tin in concentrate per year.

Geevor Tin Mines Ltd. started deepening the Victory shaft and sinking a subincline to give access to the seaward extension of the Geevor lodes. Geevor also continued to develop four other lodes with encouraging results.

Marine Mining (Cornwall) Ltd. was granted permission to work the offshore alluvial tin deposits in St. Ives Bay and in the St. Agnes region. Commercial dredging operations were scheduled for late 1976.

Amalgamated Metal Corp. (AMC) and Consolidated Tin Smelters Ltd. (CTS) merged during the year, leaving AMC the dominant company. Patiño, N.V., had a controlling 50.2% interest in the new company. AMC's smelting interests include a 50.5% holding in Malaysia's Datuk Keramat Smelting Sdn. Bhd., 79% in Nigeria's Makeri Smelting Co., and 33.3% in Australia's Associated Tin Smelters Pty. Ltd.

Williams, Harvey & Co., Ltd., a CTS subsidiary placed in voluntary liquidation June 8, 1973, continued to operate on stocks of slags and residues. All creditors were paid and the company has contributed to AMC's profits. Some primary materials were treated to improve technical operations.

TECHNOLOGY

The three main problem areas that have developed in designing large capacity dredges are as follows: (1) The bucket chain; (2) the ore treatment plant; and (3) the tailings disposal. Efforts to resolve them were discussed by IHC Holland mining engineers.[4]

Continued research on froth flotation of cassiterite yielded several patentable processes.[5] Methods for roasting [6] and volatilizing [7] tin ores were patented.

A means of fabricating columbium-tin superconducting cable was developed jointly by Intermagnetics General Corp. and General Electric Co.[8] Previously, the use of columbium-tin alloys had been limited because of brittleness. Superconductors are required to develop major new sources of energy.

Several petroleum companies were granted patents for platinum-tin catalysts used in hydrocarbon refining.[9] Tin contents of the catalysts vary from 0.01% to 5%.

A new class of organotin stabilizer for polyvinyl chloride (PVC) was developed in the U.K.[10] The stabilizers were claimed to impart excellent heat stability and low odor to the PVC. Additionally, low volatility during processing improved safety for workers.

The range of actual and potential uses for the tin oxide-antimony oxide system was reviewed.[11] Applications include areas as diverse as glass melting, ceramic glaze pigmenting, electrically conductive glass manufacturing, industrial organic compound synthesis, and ion exchange mediums for the nuclear energy field.

After enactment of legislation prohibiting sale of flammable carpets in the United States, tin-based flame retardants have been used in limited applications to enable sheepskin rugs to pass the flammability tests.[12] The tin compounds have economic and technical advantages in applications where the flame retardant can be applied by spraying the tips of the wool pile.

A U.S. firm introduced terne-coated stainless steel.[13] A.I.S.I. Type 304 stainless steel is coated on both sides with a lead-20% tin terne alloy. Its advantages were claimed to be extremely long life, solderability, and formability. The terne coated stainless steel is particularly well suited for roofing.

Titanium

By F. W. Wessel[1]

Production of both sponge and ingot titanium declined throughout the year, although ingot production seemed to have bottomed out by yearend. Sponge inventories climbed from 3,822 tons to 5,689 tons, 60% in the hands of producers, at yearend. Demand for pigment continued its 1974 decline through March, but strengthened during the spring and summer.

Ilmenite production and imports of natural rutile declined 4% and 14%, respectively, but imports of ilmenite and of synthetic rutile increased 48% and 12%, respectively.

Except for rutile, prices were generally higher than in 1974. Effective prices for rutile were about $350 per metric ton f.o.b. Australian mines at yearend. The price of domestic sponge increased 10% in August, and pigment prices advanced 9% in the same month.

r Revised.

[1] Excludes United States production data in order to avoid disclosing company confidential data.

Legislation and Government Programs.—In June, the General Services Administration (GSA) offered 1 million pounds of titanium sponge from the stockpile. No acceptable bids were received.

The Environmental Protection Agency (EPA), noting the absence of opposing opinion, amended 86 Stat. 816, Pub. L. 92–500 (33 U.S.C. 1215, 1311, 1314 (b), 1361 (a)), 40 CFR, Chapter I, Subchapter N, Section 415.220 of the Federal Water Pollution Control Act to read as follows: "The provisions of this subpart are applicable to discharges resulting from the production of titanium dioxide by the sulfate process and by the chloride process. The provisions of this subpart are not applicable to the wastes resulting from discharges from production by processes in which beneficiation of raw ilmenite ore and chlorination are inseparably combined in the same process step." [2]

DOMESTIC PRODUCTION

Concentrates.—Production and shipments of ilmenite concentrate decreased 4% and 7%, respectively, the second consecutive decline for both categories. Titanium dioxide contained in concentrates shipped was 7% less than in 1974; TiO_2 content increased fractionally to 57.6%. The 150% increase in production at the Titanium Enterprises mine, Green Cove Springs, Fla., and the 60% increase in production by Humphreys Mining Co., was insufficient to offset decreases of 4% to 21% at the mines of NL Industries, Inc., Tahawus, N.Y.; E. I. du Pont de Nemours & Co., Inc., Starke and Highland, Fla.; and ASARCO, Inc. and SCM Corp., Glidden-Durkee Div., both near Lakehurst, N.J. The Humphreys Mining Co. production was the result of nearly a full year of operation at Boulogne, Fla.; the 1974 total represented the last 6 months of mining at Folkston, Ga., before moving the mining equipment.

In September, Ethyl Corp. purchased 572 acres of land near its heavy-sand deposit in Henry County, Tenn. At about the same time, the company concluded its feasibility study. Plans for construction and operation were recessed pending revival of the titanium market.

Table 2.—Production and mine shipments of ilmenite concentrates [1] from domestic ores in the United States

Year	Production (short tons, gross weight)	Shipments: Short tons (gross weight)	Shipments: TiO_2 content (short tons)	Shipments: Value (thousands)

r Revised.

[1] Includes a mixed product containing rutile, leucoxene, and altered ilmenite.

Ferroalloys.—Shieldalloy Corp. at Newfield, N.J., continued as the sole producer of ferrotitanium in the country; as before, most of the production was in the titanium content range of 40% or higher. Foote Mineral Co. continued to produce Grainal alloys, which contain minor quantities of titanium.

Metal.—Production of titanium sponge decreased gradually during 1975; the year's production was 5% less than in 1974, although still greater than the 1973 production. However, even though imports were 40% less in 1975, yearend inventories were 48% greater than at yearend 1974. Ingot production declined 29% during the year.

Sponge producing companies were Titanium Metals Corp. of America (TMCA), Henderson, Nev., owned by NL Industries, Inc. and Allegheny-Ludlum Steel Corp.; and RMI Co., Ashtabula, Ohio, owned by National Distillers & Chemical Corp. and United States Steel Corp. As in previous years, the following nine companies produced ingot:

New orders for mill products began to slow as early as February, and stretchouts and a few cancellations appeared. Consumers' inventories of mill products seemed to be the major cause of the slump. This was the case principally in the aircraft field; nonaerospace demand was holding up well.

In June, TMCA announced plans for a 20% increase in melting capacity and a pilot cell for experimental electrolytic titanium production, both at Henderson, and doubled capacity for production of welded tubing at Toronto, Ohio.

Pigment.—Pigment production was 23% less than in 1974. Shipments were down 24%, and value of shipments decreased 20%. Rutile pigment accounted for 79% of total production and was produced by all seven manufacturers. Five companies produced anatase pigment.

At Edge Moor, Del., E. I. du Pont de Nemours & Co., Inc., phased out its last sulfate process unit in December 1974; the 80,000-ton-per-year chloride-process unit, built as a replacement, began production in January 1975. Du Pont's capacity for pigment at Edge Moor is now 160,000 tons per year. The company is barging plant effluent to sea as a temporary disposal measure, while developing alternate treatment methods. A facility for

separating ferric chloride from the pigment plant effluent was already in operation. Ferric chloride is useful in water purification, but a demand for 250,000 tons per year would be needed to eliminate 75% of the ocean dumping. The company was also testing a process more or less parallel to recent work done by the Bureau of Mines, in which waste chlorides are oxidized, leaving a high iron content solid and permitting the recycle of chlorine.

One of the two chloride-process units at Edge Moor was closed for 20 days during the year to find and repair a major leak. Loss of production was estimated at 3,500 tons of product.

Du Pont was reported in April to have decided to proceed with construction of a chloride-process plant of 130,000-ton-per-year capacity at DeLisle, Miss. The target date for completion is in the second half of 1978. NL Industries closed its Sayreville, N.J., sulfate-process plant for about 6 weeks to reduce inventories. American Cyanamid Co. closed two of its three units in Savannah, Ga., during January for the same purpose.

The effluent treatment plant of American Cyanamid Co. began operations in 1975. Three acid rejects, at 20% sulfuric acid, pH 0.5, and pH 4, respectively, are treated with limestone and slaked lime. Carbon dioxide evolves and is collected and sold; gypsum is precipitated and filtered out, and the remaining impurities precipitated by pH adjustment as metal hydroxides. The gypsum is of high enough purity to be salable. Cyanamid estimates a cost of $60 to $80 per ton of pigment for effluent treatment.

Construction of Kerr-McGee Chemical Co.'s synthetic rutile facility at Mobile, Ala., continued during the year. When complete, its output is estimated at 110,000 tons per year. As soon as production from this plant makes it possible, Kerr-McGee's pigment plant at Hamilton, Miss., will use synthetic rutile as a feedstock for 50,000 tons of pigment production per year.

CONSUMPTION AND USES

Concentrates.—Consumption of ilmenite, rutile, and titanium slag decreased 12%, 21%, and 42%, respectively, from 1974 levels.

Metal.—Consumption of sponge and ingot decreased 34% and 22%, respectively. Apparent net shipments of mill products declined 10%. The downturn stemmed primarily from a slump in commercial aircraft production, which at yearend gave no sign of ending. Demand for titanium for use in military aircraft was steady, but increased usage in this application, while reasonably certain, is indefinite as to time. Some gains in industrial demand were evident, and gains in titanium castings for both industrial and aerospace uses were substantial.

The strongest demand for titanium from the industrial sector emerged from power installations and from the chemical process industries. It was reported about midyear that 25 powerplants had titanium condenser tubing installed, on order, or specified. Titanium was being used for the internal fittings of cooling towers. Use of titanium cathodes in copper refining, first tried in 1960, has been steadily increasing as the technology becomes better understood.

Table 5.—Consumption of titanium concentrates in the United States, by product
(Short tons)

Year and product	Ilmenite [1]		Titanium slag		Rutile	
	Gross weight	TiO_2 content [e]	Gross weight	TiO_2 content [e]	Gross weight	TiO_2 content [e]

In the aircraft field, British Aircraft Corp. was reportedly replacing steel with titanium castings on engine mounts in Jaguar planes. Pratt & Whitney Division of Colt Industries, Inc. reported 900 pounds of titanium in each of its F100 turbofan engines.

Carbides.—A domestic manufacturer of carbide cutting tools predicted major gains by cemented titanium carbide in steel-cutting tools by 1985. Several larger companies whose operations include extensive metalworking announced full-scale or experimental use of titanium carbide in place of tungsten carbide. In Japan, Toyo Soda Manufacturing Co. Ltd. began test production of titanium carbides by a newly developed process. Feedstock is understood to be titanium trichloride.

Pigment.—Preliminary figures showed a 24% decrease in shipments. Domestic production of thermoplastic resins was down sharply during the year, and demand for pigment by this industry was about 41,000 tons, less than half of the 1974 requirements. Paint manufacturers used 59,000 fewer tons than in 1974. However, inventories in general were far enough depleted by March or April to bring about increased production. New orders continued to increase through August in anticipation of a rise in price.

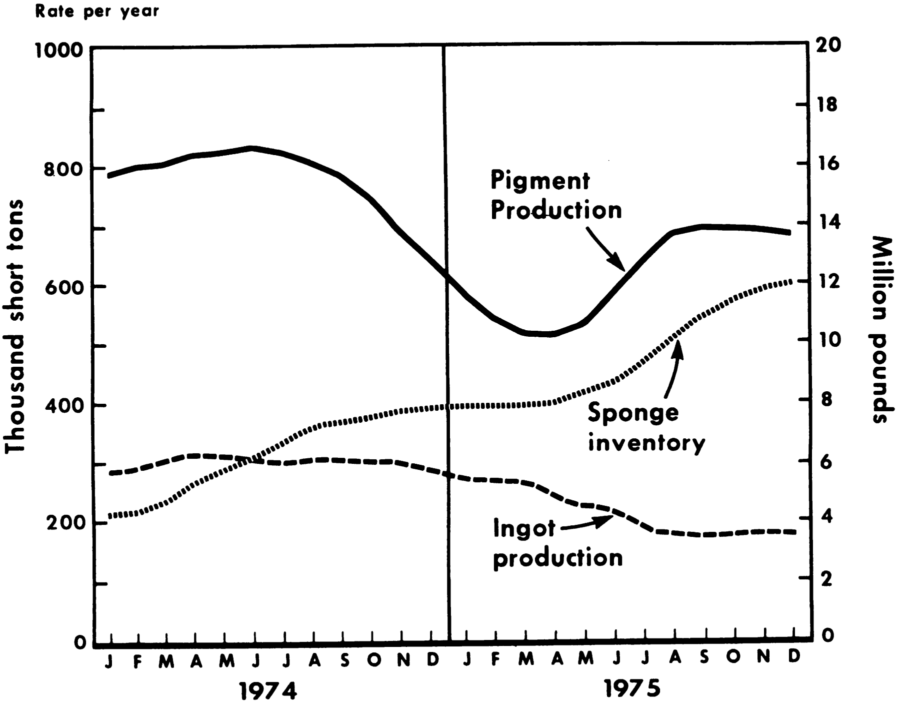

Figure 1.—Salient trends of titanium products, 1974–75.

STOCKS

In 1975, consumers began to replenish inventories of ilmenite, rutile, and slag depleted during the high-demand years of 1972–74. Increases were 13%, 29%, and 51%, respectively. Stocks of titanium sponge increased throughout 1975, and at yearend had leveled out at 48% higher than the December 1974 figure. Scrap inventories were 11% higher. Industry stocks of various grades of titanium pigment were 86,357 tons at yearend 1975, little changed from yearend 1974.

Table 7.—Stocks of titanium concentrates in the United States, December 31

(Short tons)

	Gross weight	TiO_2 content [e]
Ilmenite:		
1973	567,826	329,477
1974 [r]	572,597	325,918
1975 [p]	649,537	386,307
Titanium slag:

1975 [p]	139,571	131,740

[e] Estimate. [p] Preliminary. [r] Revised.

PRICES

Concentrates.—Price quotations for ilmenite in domestic markets remained at $55 per long ton throughout the year. Australian ilmenite prices increased to the A$15 to A$18 per long ton range at the first of the year and remained at that level, f.o.b. mines. Indian concentrates (58% to 60% TiO_2) moved from US$16.50 to US$23 per long ton, f.o.b. Indian ports, about midyear. Malayan ilmenite sold in the same price range as Australian material.

Rutile, bulk, f.o.b. cars at Atlantic, Gulf, and Great Lake ports, was quoted at $710 per short ton throughout the year. This was a spot price; long-term contracts presumably were concluded at somewhat lower figures. Declared valuations of shipments entering U.S. ports were as high as $525 per short ton in a few cases, but most valuations were less than $450. Weakness appeared early in the year in Australia, when spot prices dropped to A$375 to A$395 per metric ton. One source quoted rutile at A$290 to A$330 in January, A$270 to A$300 in September, and A$250 to A$280 in December.

Titanium slag, f.o.b. Sorel, Quebec, rose to $75 per long ton on January 1, and remained at that price until the yearend. Synthetic rutile is not yet a sufficiently standard item of commerce to warrant price quotations, but shipments from Australia, Japan, India, and Taiwan averaged about $200 per short ton, c.i.f.

Metal.—Domestic sponge began the year at $2.45 per pound, but was raised to $2.70 on August 1, ending the year at that level. GSA offered about 1 million pounds of sponge for sale, but bids opened June 25 contained no acceptable offers. Japanese sponge began the year at $2.85 per pound, but decreased to the $2.65 to $2.70 range at midyear, where it remained through the yearend. Titanium mill product prices were increased substantially in January; a further small increase took place in June.

Pigment.—An attempt to raise prices early in the year was not supported, but rising costs of energy and chlorine, and additional costs from pollution control activities, put upward pressure on prices in the face of a declining market. The market, however, reached its low point in early spring, and a price increase of 3½ cents per pound was announced, effective early in August, for all grades of pigment. Yearend prices, with minor variations, were 38½ cents per pound for anatase pigment and 43½ cents per pound for rutile pigment.

FOREIGN TRADE

Titanium dioxide exports in 1975 amounted to 15,807 tons, about half of the 1974 total. Of the year's total, Canada took 14.2%, Venezuela 14.0%, Brazil 6.3%, other Latin America and West Indies nations 22.6%, West Germany 5.1%, Western Europe 7.0%, Japan and the Republic of Korea 9.0% each, and other Far Eastern countries 9.7%.

Exports of unwrought, waste, and scrap titanium were 8.5% less than in 1974; 32% went to Belgium, 28% to the United Kingdom, and 16% to Italy. The average valuation was 88 cents per pound, 10 cents less than in 1974. Exports of wrought titanium were 11% greater than in the previous year.

Imports of ilmenite from Australia in 1975 were 52% greater than in 1974. Imports of Sorel slag were 10% less than in 1974. Imports of natural rutile declined 14%, but imports of synthetic rutile were 12% greater than 1974 levels.

Imports of unwrought, waste, and scrap titanium were about half those of 1974. Of the total, 4,190 tons was sponge, which came from Japan (2,404 tons), the U.S.S.R. (1,313 tons), and the United Kingdom (473 tons). The sponge shipments bore an average declared valuation of $1.89, $1.47, and $1.29 per pound, respectively.

Imports of pigment came to 25,918 tons during the year, and constituted 4% of domestic consumption.

WORLD REVIEW

Australia.—A meeting of representatives of the Department of Minerals and Energy and of the Australian mineral sands industry took place on June 6. The following press statement was issued:

"They (the producers) have resolved that in the best interests of consumers and the balanced development of the Australian mineral sands industry, they will arrange the supply of mineral sand products in a manner that will allow a stable long term supply of these commodities at reasonable prices commensurate with their value.

"To that end, the Department of Minerals and Energy and the industry have undertaken to examine urgently all current and future aspects of the industry in order to determine demand and pricing patterns and to state a policy including pricing of mineral sand products."

This was interpreted in some quarters as approaching the formation of a cartel, which was vigorously denied by the 14 major Australian producers.

The Western Australian Minister for Mines in February stated that the new estimate of reserves in the State totaled 80.4 million metric tons of heavy sands. Geographically, 37.1 million tons are in the Eneabba district, 32.5 million tons are in the Capel district, and 10.7 million tons at scattered locations. The total includes 51.7 million tons of ilmenite, 3.9 million tons of rutile, 10.8 million tons of zircon, and 14.0 million tons of other minerals.

[e] Estimate. [p] Preliminary. [r] Revised. W Withheld to avoid disclosing individual company confidential data.

[1] In addition to the countries listed, the U.S.S.R. and the Republic of Korea also produce titanium concentrates, but available information is inadequate to make reliable estimates of output levels.

[2] Titaniferous slag production in Canada and Japan is reported separately. Ilmenite produced in Canada goes almost entirely into slag production; separate figures are not available.

[3] Includes leucoxene.

[4] Exports.

[5] Includes a mixed product containing ilmenite, leucoxene, and rutile.

[6] Does not contain United States production in order to avoid disclosing individual company data.

[7] Contains 70% to 72% TiO_2.

In the Capel district, producers include Western Titanium, Ltd., Westralian Sands, Ltd., Cable Sands Pty., Western Mineral Sands, Pty., Ltd., and Mid-East Minerals, N.L. In the Eneabba district, A. V. Jennings Mining Co. and Allied Eneabba Pty., Ltd. came into full production during the last half of 1975; Western Titanium was building a plant to begin operation in 1976, and a fourth company, Ilmenite Pty., Ltd., while holding mineral lands, was inactive. At Jurien Bay, WMC Minerals Sands engaged in shakedown operation of its new plant. The joint venture of Westralian Sands and Lennard Oil, Ltd. at Gingin was inactive pending market improvement.

Western Titanium, at its new plant in the Eneabba area, expects to be in full production early in 1977, and to produce 150,000 tons of ilmenite, 30,000 tons of rutile, and 70,000 tons of zircon per year. The company is 85% owned by Consolidated Gold Fields Ltd. of Australia.

In 1974, Westralian Sands introduced a new product, HYTI 68, an ilmenite-leucoxene concentrate containing 68% TiO_2.

After some early difficulties, A. V. Jennings Mining Ltd. reached capacity production about midyear. Annual production of 40,000 tons of rutile, 160,000 tons of ilmenite, and 30,000 tons of zircon is scheduled.

Allied Eneabba Pty., Ltd., owned 25% of E. I. du Pont de Nemours & Co., Inc., began operations in August. Reserves are estimated at 8.54 million tons proven sands and 30.57 million tons of probable sands. Fluor Australia Pty., Ltd., contracted for plant construction and housing.

Late in 1974, Western Mining Corp., Ltd., exercised its option on the Jurien Bay heavy mineral deposit owned by Black Sands, Ltd., and began building a mining and concentrating plant. The company, jointly with Mitsubishi Chemical Industries, Ltd., was also considering construction of a synthetic rutile plant at the mine site.

Western Titanium produced 34,931 metric tons of synthetic rutile at its new 38,500-ton plant in its 1974 fiscal year ending June 30. The company closed its older 14,000-ton plant because of weakening demand, rising costs, and delayed official approval for exports. The plant had produced 11,400 tons of synthetic rutile in its 1974 fiscal year.

Rutile & Zircon Mines (Newcastle) Ltd. announced a joint feasibility study with Akzo Zout Chemie, of the Netherlands, for upgrading ilmenite by a new high-temperature chlorination process. A pilot plant at Mt. Morgan, Queensland, will be used.

DM Minerals, a joint venture of Murphyores Holdings, Ltd., and Dillingham Mining Corp. of Australia, Ltd., began operation of its mining plant on Fraser Island about midyear. Environmental groups, to some extent supported by the Australian Government, continued to oppose the mining operation.

Australian pigment producers were proceeding with major expansion plans. Laporte Australia, Ltd., announced its intention to expand capacity of its plant at Bunbury from 24,000 tons to 40,000 tons per year. Tioxide Australia Pty., Ltd., owned by British Titan Products, Ltd., will expand its plant capacity at Burnie from 29,000 tons to 35,000 tons per year.

Brazil.—Early in the year, Cia. Vale do Rio Doce announced plans for a major phosphate fertilizer plant at Tapira, Minas Gerais, a major byproduct of which will be anatase. Reserves were said to contain 45 million tons of TiO_2. Association in the titanium venture with the Japanese Ishihara group was a possibility. A pigment plant, if constructed, will be operative in 1978 or early 1979.

Canada.—Construction of the 22,000 ton synthetic rutile pilot plant of the Canadian Tiron Chemical Corp. at Pointe-aux-Trembles, Quebec, was said to be nearing completion in February. Plant capacity was given at 22,000 tons per year. Ore will be obtained from the St. Urbain district. Gulf Titanium, Ltd., was reportedly raising funds to construct a similar but smaller plant.

Quebec Iron and Titanium Corp. reported production of 738,000 tons of Sorel slag from 1,796,200 tons of titaniferous iron ore. Production was less than normal because of a breakdown of one of the smelting furnaces. A 2-week strike at Sorel also contributed to the decrease.

European Economic Community (EEC).—The EEC Commission has drafted a regulation, subject to approval of the Council of Ministers, requiring a 95%

reduction of sulfate-process pigment plant effluents within 10 years after the regulation becomes official. The timetable requires member states to apply abatement methods within 18 months. The Commission did not prescribe the abatement techniques to be used. Based on total European production of pigment, 87% of effluent is now discharged into the North Sea and the English Channel.

Ireland.—The Du Pont company relinquished its option on industrial land on tidewater at Ringaskiddy, County Cork. Plans for construction of a plant to make 100,000 tons per year of a titanium intermediate have been postponed indefinitely.

Italy.—After efforts to handle waste from its sulfate-process pigment plant at Scarlino proved ineffective, Montecatini-Edison, S.p.A. suspended operations. High plant and operating costs forecast for a treatment plant, for which technology was provided by New Jersey Zinc Co., caused abandonment of this project.

Netherlands.—B.V. Titaandioxydefabrick Tiofine, a pigment producer partly owned by American Cyanamid Co., closed its plant near Rotterdam for 6 weeks early in the year for inventory adjustment, following similar action by other producers in Western Europe.

United Kingdom.—Laporte Industries (Holdings) Ltd., operating its Stallingborough pigment plant at half capacity, laid off employees at the first of the year. The company's report for the first half-year confirmed a 50% sales volume, and expected no improvement through the yearend. British Titan, Ltd., similarly operated at half capacity throughout the year at its plant at Teesside.

India.—Reports in August dealt with construction, by Indian Rare Earths, Ltd., of a sand treatment plant at Gopalpur in southern Orissa. Monazite production was the primary purpose of the plant, but it is scheduled also to produce 240,000 tons of ilmenite and 10,000 tons of rutile annually.

Japan.—Toho Titanium Co., Ltd., and Osaka Titanium Co. produced 8,358 short tons of sponge in 1975, a decrease of 15% from 1974 production. Exports of sponge and of fabricated products through July were 1,864 tons and 587 tons, respectively; the United States received 78% of the sponge, while the Netherlands and other Western European nations received 20%. Domestic consumption of sponge, almost all for industrial uses, continued slowly to increase.

In March, negotiations between Mitsubishi Metal Corp. and an as yet unidentified United States company with ilmenite holdings were reported. A 5,000 to 6,000 ton per year production of synthetic rutile in the United States was being considered.

Malaysia.—Sakai Trading Co., jointly with Klöckner-Werke AG and Malaysian interests, were reported forming a company to develop a 2- to 3-million-ton ilmenite deposit in northeast Malaysia. Production of 10,000 tons is targeted for 1976, and 50,000 tons per year thereafter.

Straits Trading Co., Ltd., announced it would take 30% of the shares of Malaysian Titanium Corp., which intends building a 55,000-ton-per-year synthetic rutile plant in Ipoh. Tailings from Straits' tin smelter will be the principal source of ilmenite.

Sakai Chemical Industry Co. and Toyo Soda Manufacturing Co. jointly formed Shin-Nanyo Titanium Co. to produce titanium pigment. Technology of the Kerr-McGee Chemical Co. will be used.

Sierra Leone.—Representatives of the Sierra Leone Government, Bethlehem Steel Corp. and Nord Resources Co. reached final agreement on May 22 on plans to mine rutile at Gbangbama. The agreement was ratified by the Sierra Leone Parliament on July 3. A company named Sierra Rutile, Ltd., of which Bethlehem had an 80% interest, was formed to conduct operations, which are to come onstream late in 1977. Sierra Rutile hopes for an eventual annual rate of 100,000 to 125,000 tons of rutile from a deposit which contains 3 million tons.

The predecessor corporation at this deposit was Sherbro Minerals Co., Ltd., jointly owned by British Titan Products, Ltd., and Pittsburgh Plate Glass Co. Its leases were relinquished upon declaring bankruptcy in 1971. Leases at Bonthe and Moyamba were acquired by a joint subsidiary of Bayer A.G. and Preussag Metall. The subsidiary, Bayer-Preussag Mining Co., resumed mining on these leases in 1973, and was expected to construct a pilot plant in 1976.

South Africa, Republic of.—Concessions for prospecting coastal heavy sand deposits between Richards Bay and the Mozambique border reportedly have been issued to

United States Steel International Inc. and New Jersey Zinc Exploration Co. Objections on environmental grounds are in full course, but do not include the Richards Bay operation of Quebec Iron and Titanium Corp., Ltd., the South African government, and Union Corp. Ltd., which has been pronounced free of environmental hazard. These companies continued their planned development through the year.

Spain.—Titanio, S.A., received official approval to build a sulfuric acid plant of 330,000-tons-per-year capacity next to its pigment plant, which is now under construction.

Taiwan.—The first production unit of the synthetic rutile plant of Taiwan Alkali Co. at Kaohsiung was completed in July, although some shipments were made earlier. A second 15,000-ton unit is under construction.

TECHNOLOGY

The U.S. Geological Survey, the geological surveys of Georgia, North Carolina, and South Carolina, and the Coastal Plans Regional Commission conducted aerial radioactivity surveys over the three States. The results suggested anomalous concentrations of heavy sands in several places, notably in southeastern Georgia.

Energy requirements for producing titanium metal and pigment with various feed materials and by various processes were included in a report to the Bureau of Mines by Battelle Columbus Laboratories.[3]

Significant papers were published on production of synthetic rutile[4], direct chlorination of ilmenite[5], fused-salt electrodeposition of titanium[6], and recovery of chlorine and iron oxide from ferric chloride[7]; the latter is important to effluent control. Titanium dioxide was suggested for use in emission control of automobile exhausts.[8]

Du Pont introduced a scaled-down titanium dioxide slurry dispenser for the use of intermediate-scale consumers. Containing 5,000 gallons, it may be refilled from tank trucks.

Grumann Aerospace Corp. introduced a combination of forming and welding techniques to produce work requiring less machining and consequently producing less scrap. Diffusion bonding was being used by Rockwell International Corp., and a process called isothermal forging was developed by the Air Force Materials Laboratory, with substantially the same purpose in mind.

The first International Titanium Casting seminar took place in London, England, in 1974; discussions included applicability, engineering design, and quality control.

Comprehensive engineering specifications and properties of titanium alloys were published in manual form for the use of design engineers.[9]

A problem in processing and recycling titanium scrap became evident during the year when defective ingots were found to have a high content of yttrium, and yttrium oxide inclusions appeared in otherwise sound ingots. Acceptance standards were amended to include a maximum yttrium content of 30 ppm.

Bureau of Mines researchers published reports related to titanium during the year.[10]

Tungsten

By Richard F. Stevens, Jr.[1]

Domestic production and consumption of tungsten concentrate fell 24% and 14% to 5.6 and 14.0 million pounds, respectively, compared with that of 1974. Over 95% of the domestic concentrate production was obtained from two essentially continuous operations, one in California and one in Colorado. Production and consumption of ammonium paratungstate decreased 30% and 34%, respectively, while production and consumption of tungsten products in 1975 each fell 37%. Imports for consumption of tungsten concentrate decreased 41% to 6.6 million pounds while exports of tungsten concentrate, from sales of Government stockpile excesses, rose 11% to 1.3 million pounds of contained tungsten in 1975. Estimated world production of tungsten concentrate rose 1% to 82.6 million pounds during the year.

The reported price of tungsten concentrate shipments, f.o.b. domestic mines and custom mills, increased 11% and averaged $84 per short ton unit.

Legislation and Government Programs.—During the year, the General Services Administration (GSA) continued to sell excess stockpiled tungsten concentrate on the basis of monthly sealed bids. GSA offered material at a disposal rate of 500,000 pounds of contained tungsten per month and sold nearly 2.8 million pounds of concentrate during 1975; 1,337,064 pounds for domestic use, and 1,437,663 pounds for export. The material released for domestic use was sold at prices, ex-duty, ranging from $74.78 to $88.66 per short ton unit. Material for export was sold at prices, also ex-duty, from $76.05 to $89.75 per short ton unit. In addition, 478,713 pounds of tungsten concentrate were awarded in February at an average price of $87.79 per short ton unit, and 376,251 pounds of concentrate were released in May at a price of $86.52 per short to unit, both for use in defense contracts. In December, 504,865 pounds of concentrate was sold to the Government of Israel. This material was to be withdrawn over a 10-month period.

A Congressional bill (H.R. 2826), to temporarily suspend the import duty on tungsten concentrate and on other material in chief value of tungsten, was introduced February 5, 1975, and hearings were held by the Subcommittee on Trade of the House Ways and Means Committee. By yearend, no action had been taken, and the bill was pending before the subcommittee.

Early in 1975, the U.S. International Trade Commission held hearings throughout the United States to provide data for a staff study on the economic effects of tungsten tariff reductions. A report was sent to the Office of the Special Representative for Trade Negotiations and to the President. The report was transmitted to U.S. tariff negotiators in Geneva, Switzerland, attending meetings of the GATT (General Agreement on Tariffs and Trade).

DOMESTIC PRODUCTION

Domestic tungsten mine production fell 24% compared with that of 1974 and totaled 5.6 million pounds of contained tungsten during the year. Mine shipments decreased 30% to 5.5 million pounds. Although 44 mines in 8 Western States and North Carolina reported production and 43 mines reported concentrate shipments, only 2 mines were operated essentially continuously throughout 1975: The Pine Creek mine and mill of the Metals Div., Union Carbide Corp., (UCC), located northwest of Bishop, Calif., in Inyo County; and the Climax mine and mill of Climax Molybdenum Co., a division of Amax, Inc., at Climax, Colo., in Lake County. The major mineral value recovered at Pine Creek continued to be tungsten with minor amounts of byproduct molybdenum, copper, gold, and silver. UCC processed ore to produce ammonium paratungstate (APT), an intermediate form of tungsten suitable for ready conversion to tungsten metal powder. During August, the Pine Creek facilities were temporarily shut down to allow for maintenance operations.

The major mineral value recovered at Climax was molybdenum. Concentrates of tungsten, tin, and pyrite recovered as coproducts were largely dependent upon the rate of molybdenum production. The maximum tungsten concentrate production capacity at Climax is about 2.5 million pounds of tungsten annually.

Intermittent tungsten concentrate production and/or shipments were also reported from Pima County, Ariz.; Fresno, Inyo, Kern, Los Angeles, Madera, San Bernardino, San Diego, and Tulare Counties, Calif.; Valley County, Idaho; Beaverhead, Deer Lodge and Lincoln Counties, Mont.; Churchill, Elko, Mineral, Nye, Pershing, and White Pine Counties, Nev.; Vance County, N.C.; Box Elder, and Tooele Counties, Utah; and Stevens County, Wash.

The Tungsten Queen mine and mill of Ranchers Exploration & Development Corp., near Townsville in Vance County, N.C., remained closed and on "standby" status throughout the year.

UCC continued development of the Tempiute mine and mill in southern Nevada. The underground mine and adjoining surface mill was rescheduled for completion and startup in mid-1977. When operating at designed capacity, the facility will produce about 2 million pounds of tungsten per year, as well as byproduct zinc concentrate. The scheelite ore at Tempiute will be processed to tungsten semiconcentrate prior to being processed at UCC's Pine Creek (Calif.) facilities to APT.

On June 25, 1975, the tungsten milling equipment previously used by Minerals Engineering Co. at its Glen, Mont., tungsten operation was sold at auction and the plant was liquidated.

The major domestic companies engaged in tungsten operations during 1975 are listed in table 4.

Table 3.—Tungsten concentrate shipped from mines in the United States

Year	Quantity			Reported value f.o.b. mine[1]		
	Short tons 60% WO_3 basis[2]	Short ton units WO_3[3]	Tungsten content (thousand pounds)	Total (thousands)	Average per unit 60% WO_3	Average per pound of tungsten
1971	7,173	430,427	6,827	$20,184	$46.89	$2.96
1972	7,401	444,145	7,045	18,104	40.77	2.56
1973	7,418	445,051	7,059	19,154	43.04	2.71
1974	8,233	494,012	7,836	37,413	75.73	4.77
1975	5,769	346,112	5,490	29,090	84.05	5.30

[1] Values apply to finished concentrate and are in some instances f.o.b. custom mill.

[2] A short ton of 60% tungsten trioxide (WO_3) contains 951.72 pounds of tungsten.

[3] A short ton unit equals 20 pounds of tungsten trioxide (WO_3) and contains 15.862 pounds of tungsten.

Table 4.—Major producers of tungsten concentrate and principal tungsten processors in 1975

Company	Location of mine, mill, or processing plant
Producers of tungsten concentrate:	
Climax Molybdenum Co., a division of AMAX, Inc	Climax, Colo.
Ranchers Exploration & Development Corp.[1]	Townsville, N.C.
Rawhide Mining Co.[2]	Fallon, Nev.
Timm Tungsten Co	Gold Hill, Utah.
Union Carbide Corp., Metals Div.[3]	Bishop, Calif.
Processors of tungsten:[4]	
Adamas Carbide Corp	Kenilworth, N.J.
Fansteel, Inc	North Chicago, Ill.
General Electric Co	Euclid, Ohio, and Detroit, Mich.
GTE Sylvania, Inc., a subsidiary of General Telephone & Electronics Corp	Towanda, Pa.
Kennametal, Inc	Latrobe, Pa., and Fallon, Nev.
Li Tungsten Corp	Glen Cove, N.Y.
Teledyne Firth Sterling	McKeesport, Pa.
Teledyne Wah Chang Huntsville	Huntsville, Ala.
Union Carbide Corp., Metals Div	Niagara Falls, N.Y.
Westinghouse Electric Corp	Bloomfield, N.J.

[1] Produced from material mined in 1970 and 1971.
[2] Produced part of the year.
[3] At its Pine Creek mine and mill in California, Union Carbide Corp. processes ore "straight through" to ammonium paratungstate.
[4] Major consumers of intermediate tungsten products.

CONSUMPTION AND USES

Total tungsten product consumption fell 37% to 12.9 million pounds of contained tungsten during 1975. Although the quantity of tungsten used in cutting and wear-resistant materials, primarily as tungsten carbide (WC), decreased during the year, the manufacture of these materials continued to be the major tungsten product consumer. During 1975, primary end-use consumption categories were cutting and wear-resistant materials, 65%; hard-facing rods, 8%; mill products, 12%; specialty steels (tool, stainless, and alloy), 9%; superalloys, 3%; and chemicals, 2%.

The major consumption distribution of intermediate tungsten products used to make end-use items was as follows: Tungsten carbide (including cemented, crushed and cast, and crystalline), 47%; tungsten metal powder (including carbon- and hydrogen-reduced), 34%; ferrotungsten, 7%; and scrap, 5%.

Figure 2 is a simplified tungsten flow diagram showing the major processing steps, intermediate tungsten products, and major end-use items involved in the tungsten processing industry.

During the year, several special review articles were published that evaluated the use of tungsten in tungsten carbide cutting tools and in specialized elevated temperature applications.[2]

In September, the new Kysor-Dijet carbide plant was dedicated at Kalamazoo, Mich. This facility, operated by the Kysor Machine Tool Division of Kysor Industrial Corp., will produce under license, carbide grades developed by Dijet Industrial Corp. of Osaka, a leading Japanese carbide manufacturer.

Late in the year, the Carmet Co., a subsidiary of Allegheny Ludlum Industries, Inc., announced the investment of more than $1 million in new equipment to increase WC production at its plants in Madison Heights and Bad Axe, Mich.

Early in December, it was announced that General Electric Co., a major tungsten processor, and Utah International Inc. (UI), a mineral resource company, were considering a merger involving stock valued at $1.9 billion.

Late in 1975, P. R. Mallory & Co. Inc. announced plans to close its Hopkinsville, Ky., plant and to discontinue production and sales of micro-grain tungsten metal and WC powder. The Hopkinsville plant, operated by the Mallory Powder Products Co., a division of P. R. Mallory, employed 13 workers. Mallory's main operation in Indianapolis, Ind., continued production of the refractory metal powders tungsten, molybdenum, and chromium.

STOCKS

Reported stocks of tungsten concentrate held at domestic mines at yearend 1975 increased slightly, and tungsten concentrate held by consumers increased 20% during the year. Stocks of APT rose 60% over those of 1974. Producer's stocks of intermediate tungsten products increased 10% while consumers stocks of intermediate products decreased slightly as indicated in tables 1, 5, and 6.

[1] Includes melting base self-reducing tungsten.

[2] Includes both carbon-reduced and hydrogen-reduced tungsten metal powder.

[3] Includes tungsten chemicals, natural and synthetic scheelite, tungsten scrap, and other.

[4] Data may not add to totals shown because of independent rounding.

[5] Includes welding and hard-facing rods and materials and nonferrous alloys.

PRICES AND SPECIFICATIONS

The average value of tungsten concentrate shipped from domestic mines and mills, as reported to the Bureau of Mines, increased 11% compared with that of 1974 to $84.05 per short ton unit of WO_3 in 1975. Excess tungsten concentrate for domestic use was purchased from GSA during the year at prices, ex-duty, ranging from $74.78 to $88.66 per short ton unit. The price of tungsten concentrate purchased for export ranged from $76.05 to $89.75 per short ton unit. In February and in May, excess stockpiled tungsten concentrate was awarded for Government defense contracts at an average price of $87.79 and $86.52 per short ton unit, respectively.

As quoted in the Metal Bulletin (London) and reported in Metals Week, the European price of tungsten concentrate shown in table 7 remained relatively stable throughout the year and ranged from a high of £45.50 per metric ton unit in February (about $94.73 per short ton unit depending upon the prevailing rate of currency exchange) to a low of £36.75 per metric ton unit (about $73.30 per short ton unit) in July.

The price of APT delivered to large-volume contract customers was $116.50 per short ton unit at the beginning of 1975. The price decreased to $110 per short ton unit in April and to $106 per short ton unit in August. The price of "Blue Oxide" remained at $2 per short ton unit above the APT price plus a 1% surcharge to cover processing losses.

In January a conversion fee of $17 per short ton unit was charged for "toll" processing tungsten concentrate to APT at a recovery rate of about 96%. In July the tolling charge was increased to $18.50 per short ton unit.

The price of hydrogen-reduced tungsten metal powder (99.99% purity), f.o.b. shipping point, as quoted in Metals Week, ranged from $10.21 to $12.01 per pound of contained tungsten during 1975. Within this range the price was primarily dependent upon the powder particle size (Fisher number).

UCAR ferrotungsten, a proprietary high-purity ferroalloy containing 90% tungsten, was quoted at $8.20 per pound of contained tungsten through April. The price was reduced to $7.75 per pound in May and remained at this level throughout the remainder of 1975.

The price of scheelite concentrate (calcium tungstate) for direct addition to steel melts was believed to be comparable with the data reported in table 7.

Table 7.—Monthly price quotations of tungsten concentrate in 1975

Month	Wolfram and scheelite: London market, pounds sterling per metric ton unit of WO_3, 65% basis		Equivalent quotations, dollars per short ton unit of WO_3, 65% basis[1]		
	Low	High	Low	High	Average[2]
January	£37.00	£39.50	$78.31	$85.34	$80.91
February	41.00	45.50	88.39	94.73	91.58

August	40.50	42.50	77.30	82.07	79.79
September	41.00	43.50	77.07	83.27	80.51
October	40.50	43.50	75.93	81.12	78.65
November	39.50	43.50	74.25	80.74	77.45
December	42.00	44.00	77.02	80.71	78.86

[1] Equivalent high and low quotations as reported in Metals Week from biweekly Metal Bulletin (London) data: Dependent upon the prevailing rate of currency exchange.

[2] Arithmetic average of weekly quotations. Equivalent 1975 average price, excluding duty, $83.19 per short ton unit.

FOREIGN TRADE

Exports.—Tungsten concentrate exports during 1975 increased 11% compared with that of 1974 and continued to represent excess material purchased from GSA stockpiles. Ferrotungsten exports rose 74% while exports of APT more than doubled. Exports of WC powder, primarily to Canada (30%), Mexico (19%), West Germany (10%), Italy (9%), and Iran (8%), decreased 61% during 1975.

Exports of unwrought tungsten metal and alloys in crude form, waste, and scrap increased 22% to 867,798 pounds, gross weight, valued at $2,129,247.. This material was shipped primarily to West Germany (68%), Belgium-Luxembourg (8%), and Canada (7%). Tungsten and tungsten alloy powder exports decreased 43% during the year to 784,635 pounds, gross weight, valued at $5,564,426. Israel (59%), Canada (8%), West Germany and Belgium-Luxembourg (7% each), Austria and Singapore (5% each), and the United Kingdom (3%) were the principal recipients.

Exports of tungsten and tungsten alloy wire decreased 41% to 159,098 pounds, gross weight, valued at $4,701,631 in 1975 and were shipped primarily to Canada (23%), Belgium-Luxembourg (15%), Israel (11%), and Japan (9%). Wrought tungsten and tungsten alloy exports fell 21% during the year to 229,489 pounds, gross weight, valued at $2,440,968. Most of these exports were shipped to West Germany (60%), Canada (12%), and to the United Kingdom and Belgium-Luxembourg (9% each).

Imports.—Imports for consumption of tungsten concentrate fell 41% compared with that of 1974, and totaled nearly 6.6 million pounds of contained tungsten. The major suppliers were Canada (24%), Peru (13%), Bolivia (12%), Thailand (10%), and the Republic of Korea (8%).

Imports of WC during the year, primarily from West Germany (55%), Canada (25%), and Sweden (15%), decreased 1% and totaled 163,925 pounds of contained tungsten valued at $1,669,533. Imports of tungsten waste and scrap containing over 50% tungsten fell 59% during 1975 and totaled 68,959 pounds of tungsten valued at $294,139. This material was imported from the United Kingdom (26%), France (24%), West Germany (14%), Sweden (13%), Japan and Canada (8% each), and the Netherlands (7%). Imports of unwrought tungsten (except alloys) in lump, grain, and powder rose by a factor of almost eight to 201,437 pounds of contained tungsten valued at $1,865,507 and were received mainly from West Germany (71%) and Japan (25%). Wrought tungsten imports in 1975 decreased 48% and totaled 12,716 pounds valued at $1,198,891. Japan (39%) and Austria (30%) were the primary suppliers.

Imports of tungsten material classified as "metal-bearing materials in chief value of tungsten" fell 65% and totaled 70,991 pounds of contained tungsten valued at $280,186. Imports were received from Thailand (54%) and from the Republic of Korea (46%). Most of the material imported under this classification was believed to be synthetic scheelite. Imports of ammonium tungstate decreased 21% during the year and totaled 834,546 pounds of contained tungsten valued at $5,035,941. The Republic of Korea (67%) and Japan (25%) were the major suppliers.

Calcium tungstate imports in 1975, all from West Germany, increased 23% and totaled 37,819 pounds of contained tungsten valued at $576,533.

WORLD REVIEW

The Committee on Tungsten of the United Nations Conference on Trade and Development (UNCTAD) met in late July 1975 to discuss methods of stabilizing world tungsten prices with a system of minimum and maximum prices. The Committee staff continued to canvass, tabulate, and publish detailed statistics on tungsten production, consumption, and trade in its quarterly bulletin, "Tungsten Statistics."[3] Copies of these reports are available from the United Nations Sales Section, Palais de Nations, CH-1211, Geneva 10, Switzerland, at a price of $3 each.

A meeting of several major world tungsten producers was held in La Paz, Bolivia, in April 1975 at which the Primary Tungsten Association (PTA) was established.[4] The PTA is comprised of the Associacion Nacional de Mineros Medianos, Cámara Nacional de Minería, and Corporación Minera de Bolivia (all from Bolivia); Beralt Tin and Wolfram (Portugal) SARL, and Minas de Borralha (Portugal); Minero Perú Commercial (Peru); Peko-Wallsend Ltd. (Australia); Mineração Acauan Indústria e Comércio S.A. (Brazil); Société Minière d'Anglade (France); Société Minière du Rwanda (Rwanda); Coto Minero Merladet S.A. and Compania Minera Santa Comba S.A. (Spain); and Société Zairoise Minière et Industrielle du Kivu (Zaire). The Siamerican Mining Enterprise Co., Ltd. (Thailand) and the China Council for the promotion of International Trade (the People's Republic of China) have observer status. PTA established its headquarters in London.

The PTA held a meeting in June prior to the intergovernmental meeting in Geneva of the UNCTAD Committee on Tungsten. The PTA's stated purpose was to develop a producer program for price stabilization and/or an international tungsten commodity agreement (such as the Lead-Zinc Study Group and the International Tin Council) to be presented before the Committee on Tungsten for UNCTAD endorsement and implementation.

Although PTA is an international group of tungsten-producing companies, as opposed to the UNCTAD Committee on Tungsten, which is an intergovernmental group, members from some countries attended both meetings.

U.S. tungsten producers were invited to attend meetings of the PTA but declined and cited U.S. antitrust regulations that prohibit participation in meetings to fix (stabilize) prices.

Comprehensive evaluations of the status of WC powder metallurgy in Poland and India were released during the year.[5]

[1] In addition, the following countries may consume tungsten concentrate, but specific data are not available: Bulgaria, Canada, Denmark, Finland, Israel, Norway, Romania, Switzerland, and Yugoslavia.

[2] Production plus imports minus exports.

[3] Estimated by author.

[4] Data represents tungsten concentrate consumed to make ammonium paratungstate at APT plant adjacent to Sangdong mine and mill.

Primary Source: UNCTAD Committee on Tungsten quarterly reports "Tungsten Statistics" and Annual Company Reports.

Australia.—King Island Scheelite, Ltd., a subsidiary of Peko-Wallsend Ltd., continued to account for most of the Australian tungsten concentrate production from Scheelite ore grading 0.57% WO_3 at its underground operation on King Island, Tasmania.[6] Other minor reported tungsten production was from wolframite ores in Tasmania, Queensland, New South Wales, and Victoria. Some tungsten deposits also exist in Western Australia. At yearend, tungsten resources at King Island were increased to 7.7 million tons grading 0.8% WO_3.

Bolivia.—Empresa Nacional de Fundiciones (ENAF) evaluated the possibility of constructing a tungsten processing plant in Viacha about 10 miles south of La Paz.[7] Initial plans indicate that the plant would be operated as a joint venture between ENAF and International Mining Co. with technical assistance from the United States.

Brazil.—Mineração Tomaz Salustino SA continued to mine tungsten concentrate in Rio Grande do Norte. Brejui Mineração e Metallurgia SA was formed to extract synthetic scheelite from tungsten mine tailings. A plant was scheduled to be constructed in 1976 to process the tailings.

A review of a detailed report on the Brazilian ferroalloy industry by Associação Brasileira de Produtores de Ferro Ligas (ABRAFE), including long-term ferroalloy forecasts, was published.[8] The review indicated that Brazil was close to self-sufficiency in the production of ferrotungsten and would continue in this position into the 1980's. Brazil may even become a net exporter in the future.

Canada.—Tungsten concentrate produced by the Canada Tungsten Mining Corp. Ltd. (CTMC) at Tungsten, Northwest Territories, decreased 8% compared with that of 1974 and totaled 2.6 million pounds of tungsten in 1975.[9] No byproduct copper concentrate was recovered during the year. The overall WO_3 recovery decreased slightly to 71.1% compared with 71.4% in 1974. The concentrator was operational 92.7% of the time and averaged 490 tons per day.

Because of metallurgical problems created by the presence of talc in the ore, scheelite recovery was lower than anticipated. Many circuit adjustments were made during the year, and improved recovery was expected in 1976. Reserves totaled 4,347,000 tons of scheelite ore grading 1.6% WO_3 and 0.23% Cu at yearend.

At Tungsten, work was started on an extension to the powerhouse and on construction of a new assay laboratory. Sections of the main access road, damaged during the severe winter of 1974, were upgraded and drainage ditches were dug.

Operations at CTMC's tungsten leach plant at North Vancouver, British Columbia, were satisfactory with an overall recovery rate of 98.3%.

Korea, Republic of.—During 1975, Korea Tungsten Mining Co., Ltd. (KTMC), continued to be the country's major tungsten producer and accounted for over 92% of the total production of the Republic of Korea. At yearend, KTMC was owned 8.7% by the Republic of Korea Government (down from 15.5% in mid-1975). Data on Korean production and stocks of tungsten concentrate and estimated production of APT are indicated in the following tabulation for 1975:

Company	Short tons (contained tungsten)		
	Concentrate		APT production[e]
	Production	Stocks	
Chongpung mine	18	NA	--
Daewha mine	11	NA	--
Korea Tungsten Mining Co.: Sangdong mine	2,481	NA	1,100
Okbang Mining Co., Ltd	48	NA	--
Samyang mine	59	NA	--
San-Nae mine	49	NA	--
Other miscellaneous mines	29	NA	--
Total	2,695	390	1,100

[e] Estimate. NA Not available.

[9] Canada Tungsten Mining Corp. Ltd. (Toronto, Canada). 1975 Annual Report. 9 pp.

Portugal.—Production of tungsten by the major Portugese tungsten producer, Beralt Tin and Wolfram (Portugal) SARL, at the Panasqueira mine decreased 5% to slightly less than 2 million pounds of contained tungsten in 1975 due to absenteeism and a brief mine shutdown due to storm damage in December.[10] Production was also affected by reduction in allowable working hours for underground workers introduced by the Secretary of State for Labor. The availability of local labor, following an influx of immigrants from Angola and Mozambique, improved, and contracts with Cape Verdean laborers were generally not renewed.

Operation of the preconcentration plant at Barroca Grande and the mill at Rio continued to operate at satisfactory tungsten recoveries. A new byproduct copper circuit at the Rio mill became operable in October.

Rhodesia, Southern.—The Messina (Transvaal) Development Co., Ltd., conducted prospecting work on a low-grade tungsten ore zone on its Beardmore claims during the year and located some new mineralization, but no new ore bodies were identified.[11] The sand retreatment dumps were depleted in June, and in July the crushing and grinding plants at the Beardsmore mine and mill were recommissioned to treat lower grade ores. A total of 13,000 tons of slimes and 30,000 tons of sands were reprocessed, and 6,200 tons of ore were milled. Tungsten recovery remained satisfactory and 120 tons of concentrate containing 44% WO_3 were produced.

South-West Africa, Territory of.—The South West Africa Company Ltd. announced plans to reopen its tin-tungsten operation at Brandberg West. Rehabilitation work on the plant, located 150 miles northwest of Windhoek, began in the latter part of 1974. By yearend 1974, 8,000 tons of ore had been stockpiled, reopening of the property was almost completed, and trial milling operations began.

Recent exploration drilling adjacent to the Brandberg West mine indicated the presence of about 660,000 tons of additional ore. Total deposits in this area are estimated at 7.3 million tons of ore containing 0.24% combined tin and tungsten.

Nord Resources Corp. continued to operate the Krantzburg scheelite mine and mill about 100 miles northwest of Windhoek and sold WO_3 concentrate to South Africa, the United States, and Western European countries during 1975.[12]

Nord drilled a new higher grade adjacent ore zone that should come into production in 1976. In addition, Nord has a larger lower grade ore zone in one area that, if worked, could be developed into a a large-scale mining operation.

Turkey.—Initial production of tungsten concentrate from Etibank's scheelite mine at Uludag near Bursa was delayed by fire in February that severely damaged the mine infrastructure. Procurement and installation of new shoring and equipment progressed, and the mine operation was scheduled to start in late 1976. Production in 1977 was expected to be about 75% of the annual rated capacity of 3,300 tons of tungsten concentrate containing about 67% WO_3.

U.S.S.R.—The Sandvik Group, headquartered in Sandviken, Sweden, signed an agreement with Stankoimport, the U.S.S.R.'s foreign trade organization, to establish a $34 million cemented carbide cutting tool plant in Russia.

Sandvik's participation will include supplying machines, equipment, and spare parts; supervising installation work; and training the personnel. The facility to be built in the Moscow district was scheduled to begin production of cemented carbide indexable inserts for cutting tools in early 1976. For several years, the Sandvik Group has also been supplying tungsten carbide tools for the Soviet auto/truck industry.

Development of an open pit tungsten-molybdenum deposit at the Tyrny-Auz complex in North Caucasus continued during the year. Exploration of a new tungsten deposit in Buryat A.S.S.R. continued throughout 1975.

TECHNOLOGY

Methods of encasing a fissionable enriched uranium oxide fuel were developed in which successive emitter layers of molybdenum (Mo), tungsten (W), and Mo-W were used. Recent developments in WC applications have included the use of tin-coated WC, WC catalysts, and hydrostatically compacted tungsten carbide-cobalt (WC-Co) powders.[13]

[12] Cruft, E. F. Tungsten in South-West Africa. Presentation to New York Society of Security Analysts. Aug. 22, 1975.

The results of a geochemical survey of the overburden of the Tungsten Queen mine in North Carolina, indicated that trace-element values in soil are related to major underlying tungsten mineralization.[14]

New ways to apply the proprietary processing operation of Dynamet Technology Inc. to the development of tungsten carbide cutting tools by isostatic pressing techniques were evaluated.[15]

Thin tungsten films were developed with a microscopic dendritic surface structure that may open a new market for tungsten in solar energy systems. International Business Machines Corp. (IBM) scientists discovered that vapor-deposited tungsten captures 96% of the sunlight that reaches the film and can retain heat at operating temperatures of 925° F. This highly efficient collecting surface could stimulate interest in solar heating technology.[16]

Studies of the morphological changes that occurred during the reduction of WO_3 to W metal powder indicated an initial reduction to large platelike whiskers of $WO_{2.72}$.[17] The formation of whiskers of $WO_{2.72}$ is the controlling step in determining the final particle size of tungsten powder.

WC rolls have been developed that are a great improvement over chilled iron or steel rolls.[18] Thermal fatigue laboratory tests and experience from other carbide applications indicated that a coarse WC grain grade was superior to medium or fine grain grades in hot rolls.

Uranium

By James H. Jolly [1]

Domestic uranium mine production (in terms of U_3O_8) was lower in 1975 owing principally to the mining of lower grade ores. Mining activity continued high and the gross ore tonnage produced was greater than that in 1974. The tonnage of ore milled increased significantly; however, the production of uranium increased less than 1% owing to the lower grade of ore milled. Fifteen conventional mills and 2 additional plants for recovery of uranium from in situ leach solutions and from phosphoric acid operated in 1975, compared with 14 conventional mills operating in 1974.

Although mine and mill production continued near the previous year's level, production was expected to increase rapidly in the next few years. A number of major new mines and associated mills were planned or under construction primarily in New Mexico and Wyoming, which together accounted for about three-fourths of the total domestic mine production. Several operating mills were expanded to increase capacity, and others were undergoing modernization and expansion. Increased emphasis was placed on recovering uranium by solution mining; one operation in Texas started commercial production in 1975 and others were planned. The commercial recovery of uranium from Florida phosphate also began in 1975; additional recovery modules were planned and a central processing plant was under construction.

Exploration for uranium continued on a large scale, although the success ratio was unimproved. Higher uranium prices increased interest in the development of lower grade resources. According to the Energy Research and Development Administration (ERDA),[2] reserves at forward costs to $30 per pound of U_3O_8 increased by 40,000 tons whereas lower cost reserves ($8 and $10 per pound of U_3O_8) declined owing to the relatively steep rate of inflation affecting production costs. The ERDA office at Grand Junction, Colo., continued its national uranium resource evaluation program, which is designed to assess the country's potential uranium resources.

In other sectors of the nuclear fuel cycle, legislation to aid the development of private uranium enrichment facilities and to build an additional Government diffusion plant was proposed. Programs to improve operations and increase capacity at the three Government enrichment plants continued. Although a nuclear fuel reprocessing facility was nearing completion, licensing problems were expected to delay startup for several years. Waste management continued as a major concern. Long-term storage in stable geological formations continued to be the favored means of disposal.

Shortage of investment capital, concern for reactor safety, plutonium, radioactive waste, and energy conservation practices caused further delays in commercial nuclear power development. Despite these adverse factors, the industry continued to move forward. Three powerplants became operable in 1975, and 11 orders for new plants were placed. Nuclear powerplants generated about 9% of the nation's electrical energy in 1975, up from 6% in 1974. Nuclear power continued to be attractive from the economic standpoint when compared with power generation using coal and oil.

[4] Includes marketable concentrate from leaching operations.

[5] Market economies only.

[6] At yearend; maximum forward cost of $10 per pound U_3O_8.

[7] In exploration, mining, and milling, at yearend.

Principal source: Energy Research and Development Administration.

Exploration and Reserves.—According to an ERDA survey,[3] 86 companies reported expenditures of $122 million on uranium exploration activities in 1975. Foreign interests in 15 companies accounted for about 11% or $13 million of total expenditures. At yearend, 71 companies reported uranium exploration holdings of 11.8 million acres, 31% more than in 1974. During 1975, 3.8 million acres were acquired at a cost of $16.7 million. The cost per acre ranged from less than 10 cents to more than $60, averaging $4.80.

In 1975, 55,900 surface holes were drilled by 96 companies using an estimated 244 drill rigs. Total exploration and development drilling footage was about 18% more than that of 1974. Exploration costs, including drilling, access roads, site preparation, geologic and technical work, sampling, and logging ranged from $1 to $16 per foot averaging $2.90 per foot, a 40% increase over costs in 1974.

ERDA reported increases in overall domestic uranium reserves in 1975 but estimates of reserves recoverable at a cost of $10 or less per pound of U_3O_8 declined significantly owing to the affects of inflation and to reevaluation of data for certain deposits. There were 573 properties having reserves at $10 per pound of U_3O_8 and 1,819 properties having reserves at $30.

Table 4.—Domestic ore reserves at various estimated costs

Cutoff costs (per pound U_3O_8)	Tons of ore (millions) 1974	Tons of ore (millions) 1975	Average grade (percent) 1974	Average grade (percent) 1975	Tons of U_3O_8 1974	Tons of U_3O_8 1975

New Mexico and Wyoming continued to be the leading States in uranium reserves with a combined total of 83% of the $10 reserves and 85% of the $15 reserves. ERDA estimated that yearend reserves, by State, at a cost of $10 per pound of U_3O_8 were as follows:

State	Tons of ore (millions)	Grade (percent U_3O_8)	Tons of U_3O_8	Percent of total tons of U_3O_8
New Mexico	57.2	0.26	151,000	56
Wyoming	62.6	.12	[1]73,000	27
Texas	19.8	.08	[1]15,000	6
Colorado and Utah	6.3	.30	19,000	7
Other[2]	10.3	.11	12,000	4
Total	156.2	.17	270,000	100

[1] Includes low-grade reserves recoverable at $10 per pound by solution mining.

[2] Arizona, California, North Dakota, South Dakota, and Washington.

ERDA continued to expand its National Uranium Resource Evaluation (NURE) program to assess potential uranium resources throughout the United States, including Alaska. Contract aerial radiometric reconnaissance surveys were expected to cover 125 areas consisting of 741,000 line miles by 1980, using computerized, high-sensitivity, gamma-ray spectrometers and magnetic detectors. The resource program also included hydrogeochemical studies and the sampling of alluvial sediments. Participants included ERDA's national laboratories, private companies, universities, State agencies, the U.S. Geological Survey, and the Environmental Protection Agency. Data on the airborne and geochemical studies are placed on open file following completion of each survey. To meet the expanding program, NURE funds were increased from $5.7 million in fiscal 1974 to $14 million in fiscal 1975.

In August, Bendix Field Engineering Corp. became the onsite contractor for ERDA's Grand Junction Office. As such, Bendix assumed responsibility for the operation of the Grand Junction facility and for programs related to estimating national resources of uranium, identifying favorable areas for uranium exploration, developing and evaluating improved uranium exploration assessment and production technology, and administering leases on mineral lands under ERDA control.

PRODUCTION

Mine.—Gross uranium ore output was higher than that of 1974, but the average ore grade and recoverable U_3O_8 were lower. ERDA data indicated production, by State, as follows:

State	Mine production[1]	
	Ore (thousand tons)	U_3O_8 content (tons)
New Mexico	2,985	5,500
Wyoming	2,589	3,700
Other[2]	1,791	3,100
Total	7,365	12,300

[1] Does not include output of approximately 200 tons of U_3O_8 from mine waters, leaching operations, and recovery from phosphate rock processing.

[2] Colorado, Texas, Utah, and Washington; combined to avoid disclosing individual company confidential data.

About 55% of the total production of 12,300 tons of U_3O_8, was from open pit mines; 43%, from underground mines; and 2%, from other sources. There were 121 underground mines, 23 open pits, and 25 miscellaneous sources in 1975, compared with 123 underground mines, 31 open pits, and 19 miscellaneous operations in 1974.

Several large new mines were planned or under development mainly in New Mexico and Wyoming. Gulf Mineral Resources, Inc. (GMR), a division of Gulf Oil Corp., continued development on the largest and deepest uranium mine in the United States near Mt. Taylor in New Mexico. The ore body, which lies at a depth of 3,500 feet, was estimated to have reserves of 100 million pounds of U_3O_8. At yearend the 14-foot-diameter service shaft was sunk to a depth of 700 feet. Work on the main shaft began in December and was expected to be completed in 1978 at which time underground development was to begin. Commercial production was scheduled for 1981. GMR was also planning to develop its smaller and shallower uranium reserves at Mariano, N. Mex. Shaft sinking was expected in 1976 with production in 1977.

Development work at the Johnny M mine, a joint venture of Ranchers Exploration & Development Corp. (RED) and HNG Oil Co., was completed during the year. Production was expected in early 1976 at a mining rate of 800 tons ore per day. In the Church Rock area near Gallup, N. Mex., Kerr-McGee Nuclear Corp. (KMN) and United Nuclear Corp. (UNC) also had mines under development.

Phillips Petroleum Co. announced a significant uranium discovery near Crownpoint in McKinley County, N. Mex. Drilling indicated an estimated 25 million pounds of U_3O_8 in 7 million tons of ore at depths between 3,000 and 3,500 feet. Feasibility studies were underway at yearend; however, the company estimated that production could not start before 1981.

Rocky Mountain Energy Co., a joint venture of Union Pacific Corp. and Mono Power Co., planned to construct a mine-mill complex at Bear Creek, 65 miles northeast of Casper, Wyo. Construction of a 1,000-ton-per-day mill was scheduled to begin in 1976, subject to licensing by the Nuclear Regulatory Commission (NRC). Construction was expected to start in mid-1977.

Utah International, Inc. planned to develop nine pits at its Green Mountain uranium mine, located 15 miles southeast of Jeffrey City, Wyo. The company expected to start stripping operations and mine construction by mid-1976. Development of the pits, which was to involve the removal of about 100 million cubic yards of overburden, was not expected to be completed until the mid-1980's.

Development drilling in 1975 by RED substantially extended reserves (estimated at 800,000 pounds of U_3O_8) at its Small Fry mine near Moab, Utah. RED was readying the mine for production at a rate of 250 tons per day.

Atlantic Richfield Co. (50%), Dalco Oil Co. (25%), and United States Steel Corp. (25%) began commercial production at the in situ leaching operation near George West, Tex., in April.[4] Production capacity was 250,000 pounds of U_3O_8 per year; however, plans called for expansion to 1 million pounds per year after operating experience was gained.

Byproduct Uranium.—An estimated 6 million pounds of U_3O_8 were considered recoverable annually by 1979 from wet process phosphoric acid operations that use Florida phosphate rock.[5]

Uranium Recovery Corp. (URC), a subsidiary of UNC, expected to complete its 1,000-ton-per-year central uranium finishing plant at Mulberry, Fla., in early 1976 and was preparing to operate its first uranium recovery module in 1976 at the W. R. Grace & Co. (WRG) phosphoric acid facility at Barstow, Fla.[6] URC has contracted to install three additional modules, two at a new phosphoric acid plant owned by International Mineral & Chemical Corp., 10 miles west of Mulberry, and another to be added to the WRG plant in 1977. When these four units are completed, URC was expecting to recover about 1.3 million pounds of U_3O_8 per year. Other programs to recover uranium from wet process phosphoric operations were in advanced pilot plant stages, but no commitments for construction of commercial plants were announced. Companies involved in these efforts were Westinghouse Electric Corp. and Gardinier, Inc., at Gardinier's Tampa, Fla., plant; Freeport Minerals Co. at its Uncle Sam, La., plant; and Gulf Oil and Chemicals Corp. at Agrico Chemical Co.'s plant in South Pierce, Fla.

Mill.—Output of U_3O_8 in concentrate was slightly higher than in 1974 owing mainly to higher mill throughput. Fifteen conventional mills plus 2 additional processing plants were operating at the end of 1975, compared with only 14 conventional mills in 1974. The 15 mills operated at the highest average rate per mill ever attained (1,400 tons of ore per day), and the total ore processed, 7.4 million tons, was exceeded only by that of the record years of 1960 and 1961 when more than 25 mills were processing ore. Despite the high ore processing rate, production increased only slightly owing to the processing of lower grade mill feed. The mills operated at about 80% of capacity and mill recovery improved marginally, averaging slightly less than 94%. At yearend, total operable milling capacity was 28,450 tons of ore per day, an increase of 2,650 tons over that of 1974.

In 1975, Utah International, Inc. raised the capacity of its Shirley Basin, Wyo., mill from 1,200 tons per day to 1,800 tons per day primarily to enable the plant to process lower grade ores without reducing the output of uranium. Atlas Corp. was adding a new uranium-vanadium recovery circuit to its Moab, Utah, mill. The new facilities, which permit the processing of carnotite ores, were expected to be fully onstream in early 1976. The annual production of the renovated mill was to be 1 million pounds of U_3O_8 and 3 million pounds of vanadium.[7] Western Nuclear Inc. was modernizing and expanding its Jeffrey City, Wyo., mill and was to resume operations in 1976. The expansion program was scheduled to be completed in 1979, at which time the annual capacity of the mill was planned at 2 million pounds of U_3O_8.[8]

Uranium Hexafluoride (UF_6).—Two commercial operations—the Allied Chemical Corp. plant at Metropolis, Ill., and the Kerr-McGee Corp. (KMC) plant at Sequoyah, Okla.—produced UF_6 during 1975. The conversion capacities of the Allied Chemical Corp. plant and the Kerr-McGee Corp. plant were 15,430 tons and 5,510 tons of uranium per year, respectively. KMC began an expansion program to double conversion capacity by the end of 1977. According to ERDA, the available annual conversion capacity of 26,450 tons of uranium after the KMC expansion will be sufficient until about 1979.

Beker Industries Corp. announced plans in October to build a plant at Carlsbad, N. Mex., for the conversion of uranium to UF_6. The company estimated it would take 3 years to construct the plant after all economic and technical studies were completed. The plant was expected to cost $100 million and was to have a capacity of 23,500 tons of UF_6 per year.[9]

In June ERDA announced that holders of fixed commitment enrichment contracts could terminate or adjust separative work schedules. This offer was made primarily because utilities from late 1974 were experiencing slowed load growths and problems in financing new power projects, difficulties that caused marked reductions in actual requirements for enrichment services. Out of a total of 137 domestic fixed commitment contracts, holders of 96 contracts elected to slip separative work delivery schedules an average of 23 months, 21 adjusted schedules, and 4 terminated contracts. Of the foreign contracts, out of a total of 112 fixed commitment and conditional contracts, 54 delayed separative work commitments an average 29 months, 4 adjusted schedules, and 9 terminated agreements.[10]

Enriched Uranium.—ERDA reported enrichment revenues of $458.5 million in 1975 for separative work furnished under enrichment contracts. A total of nearly 9.8 million separative work units (SWU)[11] was carried out for 24 domestic and 17 foreign customers.

In June ERDA announced plans to maintain the enrichment tails assay at 0.20% U^{235} through September 30, 1977, followed by stepwise increases to 0.30% U^{235} by September 30, 1981. The increases were necessary to support the reactors under development and to provide more feed to permit additional production of enriched uranium for the ERDA reserve stockpile.

The ongoing ERDA Cascade Improvement Program and Cascade Uprating Program were expected to increase the annual SWU capacity of the Government's three enrichment plants from 17.2 million to 27.7 million by 1980 with new equipment and higher power levels. This capacity was expected to be adequate until the mid-1980's. Expansion of the Government diffusion enrichment plant at Portsmouth, Ohio, had been proposed to provide future enrichment capacity. Legislative action on the proposal was expected in 1976.

On June 25, 1975, the President proposed a program to Congress, the Nuclear Fuel Assurance Act, that would end the Government monopoly in uranium enrichment and authorize and encourage the development of uranium enrichment facilities by private industry. The proposal would lead to a competitive uranium enrichment industry in the United States and provide for future enrichment capacity with a minimum of Government funding.[12]

Four private groups have submitted proposals to ERDA for the construction and operation of privately-owned uranium enrichment facilities. CENTAR Associates, a joint venture of ENI Nuclear Co. and ARCO Nuclear Co., wholly-owned subsidiaries of Electro-Nucleonics, Inc., and Atlantic Richfield Co., respectively, planned a 3-million-SWU gas centrifuge plant to be built in stages at a total cost of about $1.1 billion. CENTAR estimated startup in 1981 and full production in 1987 if the legislation passed. Proposals for similar size gas centrifuge plants were also submitted by Exxon Nuclear Co., Inc., and by the Texas Regional Enrichment Corp. (TRENCOR), a subsidiary of Garrett Corp.

Fuel Fabrication.—Fuel fabrication orders continued to increase in 1975, despite worldwide deferral or rescheduling of major nuclear generating plants by electric utilities. Exxon Nuclear Co., Inc. was again doubling the capacity of its fuel fabrication plant in Richland, Wash.[13] A previous doubling of the plant's capacity was completed in 1974.

NRC proposed halting the issuance of licenses for use of mixed oxide fuels in light-water power reactors until 1978, when it expected to make a final decision on plutonium recycling.[14] NRC was, however, allowing limited reprocessing and use of plutonium in mixed fuels for experimental purposes.

Fuel Reprocessing.—As in 1974, there was no operable commercial spent fuel reprocessing capacity in 1975. The Barnwell, S.C., nuclear fuel plant, with a planned reprocessing capacity of 1,650 tons of uranium per year, was virtually completed during 1975 by Allied-General Nuclear Services, Inc. (AGNS). NRC, however, has not approved operation of the facility pending resolution of problems related to safeguards of plutonium, mixed-oxide fuel usage, and environmental considerations. Although licensing of the reprocessing facility was delayed, it appeared likely that NRC would approve licensing of the Barnwell fuel receiving and storage station whereby AGNS would be authorized to store irradiated nuclear fuel.[15]

Nuclear Fuel Services, Inc. (NFS) was planning to modify its West Valley, N.Y., plant to increase both storage and reprocessing capacity. The NFS plant was not expected to be licensed or operating for several years.

ERDA projections indicated a shortfall in reprocessing capacity through 1985. The situation was expected to worsen with delays in licensing of present capacity and slippages in scheduled future capacities. The major reason given for insufficient planned commercial capacity was uncertainties in Government policy and licensing requirements for plutonium recycling and waste management. Continued delays in fuel reprocessing were expected to cause possible future shortages in spent fuel storage capacity.[16] A study by the Nuclear Assurance Corp. indicated that the operations of some nuclear power units could be affected by a lack of spent fuel storage capacity by 1979. To help alleviate part of the problem, a number of manufacturers have redesigned spent-fuel storage racks to accommodate more assemblies in a typical fuel pool.[17] New designs have increased the storage capacity by factors of from 1.5 to 4 depending on the design in existing facilities and seismic requirements.

Waste Management.—Low-level commercial waste was buried at six sites in Kentucky, Nevada, South Carolina, Illinois, New York, and Washington in 1975. About 2 million cubic feet of waste was added to these sites in 1975, increasing the total buried to about 13 million cubic feet. These sites were estimated to have the capacity to handle low-level wastes until the mid-1990's. ERDA operated large land burial sites at five principal facilities for ERDA-generated waste. These sites contained about 43 million cubic feet of radioactive waste, exclusive of classified waste. About 1.3 million cubic feet were added in 1975. Leakage and migration of radioactive elements from several sites, both commercial and Government, caused environmental problems. Studies were planned by the States involved, ERDA, NRC, U.S. Geological Survey, and the Environment Protection Agency to correct the situation.

CONSUMPTION AND USES

During 1975, the domestic commercial nuclear power industry was beset by problems of raising capital and public concern for reactor safety. In addition, energy conservation practices resulted in reduced energy forecasts, which added to delays in nuclear powerplant schedules. Numerous reactor deferrals and a few cancellations were announced. All high-temperature, gas-cooled reactors (HTGR) were canceled.[18] Deferrals affected many nuclear power plants under construction or planned. As a result ERDA's short-term (to 1985) demand projections were reduced from earlier forecasts, but the long-term forecast (to 2000) was little affected. The number of plants expected to go into commercial operation by 1985 declined from 190 calculated in June to 182 as of December.

Despite adverse factors, the industry continued to move forward. Three powerplants (2,785 megawatts) became operable; 11 nuclear power generating units (13,350 megawatts) to be located at 7 power stations were planned in 1975.[19] In 1974, 30 units with a total capacity of 36,378 megawatts were planned. Domestic reactor status was as follows, at yearend:

Status	Number of installations	Capacity (megawatts electric)
Operable	[1]58	39,595
Under construction	87	88,138
Planned	93	108,995
Total	238	236,728

[1] Includes two ERDA-owned plants.

This compares with 235 units and 232,720 megawatts at yearend 1974.

Electrical consumption during 1975 increased 2% over that of 1974, according to statistics compiled by the Edison Electric Institute. The increased production of electricity was primarily attributed to rising electrical generation by nuclear powerplants, which provided nearly 9% of all electricity produced in the United States in 1975. According to an Atomic Industrial Forum (AIF) survey, the nuclear contribution reportedly represented fossil fuel savings of more than 10 billion gallons of oil or more than 55 million tons of coal. The AIF survey placed the average cost of a nuclear-generated kilowatt-hour in 1975 at 12.27 mills, 63% less than oil and 30% less than coal.

Table 9.—Current and projected domestic U_3O_8 demand[1]

1975 did not significantly improve the situation, indicating that a substantial contracting effort by uranium producers and utilities was necessary in the next 10 years.

Table 11.—Uranium fuel supply arrangements for domestic nuclear reactors [1]
(Percent of total nuclear generating capacity)

In December, NRC issued the first preliminary design approval for a standard nuclear powerplant. Two other applications for standardized design were nearly completed.[21] Standardization was expected to further increase the margin of safety and offer advantages in scheduling, construction, and operation.

Late in 1975, NRC issued a draft generic environmental statement on floating nuclear powerplants (FNPP). The statement covered the environmental considerations of siting and operating FNPP in the coastal waters of the Atlantic Ocean and the Gulf of Mexico and certain river and estuarine locations.[22] As proposed, Offshore Power Systems Inc., a joint venture of Westinghouse Electric Corp. and Tenneco Inc., planned to manufacture on an assembly line basis, eight nuclear powerplants, mounted on floating platforms, at a facility on Blount Island in Jacksonville, Fla. The completed powerplant was to be towed to the site and moored within protective breakwaters. Plans called for the first FNPP to be sited off the coast of New Jersey if approval is given.

Studies were underway on the feasibility of nuclear energy centers, which would include a concentration of nuclear powerplants, nuclear fuels manufacturing and reprocessing, and waste management, all at one site. The nuclear energy center concept was proposed to alleviate some reactor and fuel-cycle problems and provide better safeguards against undesirable diversion of plutonium or enriched uranium. A draft study of NRC indicated that nuclear energy centers containing up to 20 reactors were both feasible and practical.[23]

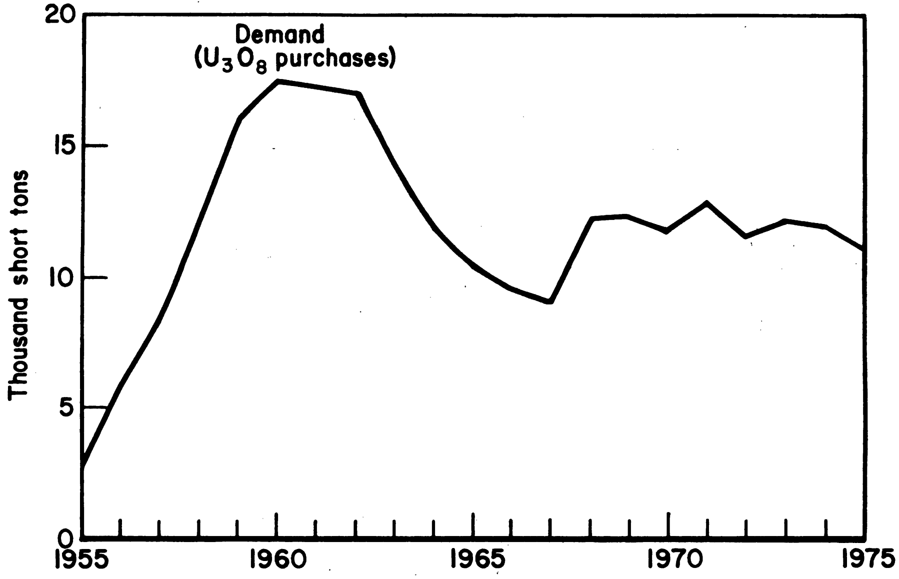

Figure 1.—Domestic uranium demand.

STOCKS

Stocks held by the producers, or milling companies, were reduced during 1975, whereas those held by the consuming industry increased by 2,400 tons of U_3O_8, as indicated in the following data provided by ERDA (in tons of U_3O_8):

	Jan. 1, 1975	Dec. 31, 1975
In ore at mills	300	200
In process at mills	400	400
In concentrate at mills	4,300	2,700
In concentrate held by utility companies, reactor manufacturers, and agents (including equivalent U_3O_8 in UF_6)	20,200	22,600
Total	25,200	25,900

A 1,100-ton inventory of foreign U_3O_8 was also reported.

The stockpile of depleted uranium continued to grow as a result of large-scale enrichment services provided for domestic and foreign customers. The ERDA tailings stockpile contained about 220,000 tons of uranium in the form of UF_6 at the end of 1975.

PRICES

The price for spot sales and future deliveries of U_3O_8 in concentrate continued to escalate during 1975. The strong sellers' market that developed in 1974 continued to be reflected in newly negotiated 1975 contracts, many of which called for prepayments, price adjustments, or payments based on prices prevailing at the time of delivery. The market was further spurred on at the end of 1975 by the announcement by Westinghouse Electric Corp. in September that the company would not be able to meet uranium contract commitments.[24]

---

[24] Chemical Week. Uranium Pact Disputed. V. 117, No. 12, Sept. 17, 1975, p. 21.

According to the Nuclear Exchange Corp. (Nuexco), the spot bid price increased from $15 per pound of U_3O_8 for delivery in January to $35 at yearend. During this period, the bid price for delivery in 1980 increased from $25.35 to $47.45 per pound.[25]

An ERDA survey indicated significantly lower U_3O_8 prices paid by reactor manufacturers and utility companies having long-term contracts.[26] According to the survey, contract prices representing 84% of commitments ranged from $6.50 to $30 per pound of U_3O_8, averaging $10.50. In 1974 the average price per pound of U_3O_8 was $7.65. An average price of $14.35 per pound of U_3O_8 was indicated by the survey for 1980.

Uranium ore was purchased by General Electric Co. at its Naturita, Colo., ore buying station for 95% of one-half the listed spot price per pound of contained U_3O_8. A minimum of 2 pounds of U_3O_8 per ton of ore was required for purchase.

The costs for enrichment services continued to rise because of increasing actual and projected costs, primarily for electric power. In fiscal 1975, the cost of electric power added about $8 per SWU to enrichment charges. Increases in operating capital and process development costs added an additional $2 per SWU. Effective August 20, 1975, ERDA increased the price per SWU for fixed-commitment contracts to $53.35 from $42.10. For requirement-type contracts, the cost was increased in December from $47.80 to $60.95 per SWU or the ceiling charge, whichever was less.

In June, ERDA forwarded to Congress draft legislation that would revise the basis for establishing prices of uranium enriching services.[27] The legislation was proposed to allow ERDA to obtain fair value for enrichment services, now based on cost recovery pricing, and to reduce the differential between Government charges and those of potential domestic private enrichment projects.

Depleted uranium metal in 300-pound ingots (Derby metal) was priced at $2 per pound.

FOREIGN TRADE

Uranium was imported in the form of U_3O_8 for conversion to UF_6 and enrichment, and as UF_6 for enrichment. Exports of the enriched uranium products are included in special nuclear materials, the quantity of which is not available. Imports of U_3O_8 concentrate were lower in 1975, but imports of other compounds, largely UF_6, were higher.

In 1975 an additional 4,400 tons of foreign uranium was contracted for, bringing the total foreign procurement to 45,400 tons. Commitments by domestic uranium producers to foreign buyers increased by 400 tons of U_3O_8 during 1975, raising the total commitment to 4,000 tons. ERDA reported that 500 tons of U_3O_8 was delivered to foreign buyers in 1975.

Restrictions on the enrichment of foreign uranium for domestic use were to continue until 1977, at which time up to 10% of a utility's uranium requirements could come from foreign sources. The allowable percentage was to be increased each year until 1984 when 100% of a utility's uranium requirements could come from imported material.

WORLD REVIEW

Nuclear power growth continued to expand, though at a more modest rate than was predicted before the 1973 oil crisis. In 1975, developed countries that had little or no energy alternatives generally continued extensive programs for the development of nuclear power, whereas those countries with coal or oil resources, tended to reduce nuclear energy projections. France, for example, maintained its nuclear program adoped in 1973 whereas the United Kingdom substantially reduced its nuclear program, directing greater attention to domestic coal and North Sea oil. Some of the developing nations also continued to formulate nuclear programs or place greater emphasis on nuclear power as a means of increasing energy supplies; however, increasing cost and capital shortages were delaying most programs.

Energy conservation practices and the downturn in world economic growth hindered growth in the industry in 1975 and influenced planning for future primary and enriched uranium supplies. Public attitudes concerning the environment, reactor safety, and plutonium and waste management were further constraints on nuclear development. The threat of nuclear weapons proliferation through diversion of nuclear fuels, facilities, and materials increasingly caused concern internationally and in 1975, affected U.S. reactor sales to countries that had not signed the Non-Proliferation Treaty.

The demand for electricity continued to grow at a low rate, with nuclear power the fastest growing electrical energy form. Worldwide, operable nuclear capacity increased from 67,943 megawatts in 1974 to 75,103 megawatts in 1975.

According to data compiled by the American Nuclear Society, 104 plants outside the United States were operable in 18 countries and 168 nuclear units were planned in 29 countries at yearend. This compares with 98 plants operable in 18 countries and 149 units planned in 27 countries at the end of 1974. Most of the planned units were scheduled for completion by 1985.

Western Europe and Japan continued to rely on enrichment services from the United States but the Europeans planned to become self-sufficient in enrichment in the mid-1980's. Urenco Ltd., a tripartite organization of the Netherlands, the United Kingdom, and West Germany, was constructing commercial gas centrifuge enrichment plants at Almelo, Netherlands, and at Capenhurst, United Kingdom. Urenco planned to have the first sections of both production plants, having capacities of 200,000 SWU, completed by early 1977. Plans called for Urenco capacity to reach 2 million SWU per year by 1982 and 10 million SWU per year by 1985. The company reportedly had $1.5 billion in orders for 25 million SWU for delivery between 1977 and 2000.[28] Eurodif, a five-nation consortium comprising France, Belgium, Iran, Italy, and Spain, continued construction of a 10-million-SWU gaseous diffusion enrichment plant at Tricastin, France. The plant was scheduled for completion in 1980. Another group, Coredif, a joint venture of Eurodif and Iran, was planning to construct a similar-sized, diffusion enrichment facility, also at Tricastin, to meet projected shortfalls in enrichment capacity in the mid-1980's. The first stage, 5 million SWU capacity, was expected to be onstream in 1985 with full production in 1988.

Others around the world were also building or planning to build enrichment pilot plants. Japan's Power Reactor and Nuclear Fuel Development Corp. (PRF) was proceeding with the construction and operation of a 50,000-SWU-capacity, pilot centrifuge enrichment plant. PRF proposed building a 500,000-SWU demonstration plant by 1984 followed by a 1-million-SWU capacity commercial plant by 1988, with capacity increasing to 4 million SWU by 1995. The Uranium Enrichment Corp. of South Africa Ltd. (UCOR) completed construction of its pilot plant at Valindaba to test a "helikon" cascade design used in conjunction with a modified jet nozzle enrichment technique. A decision to construct a commercial scale plant, estimated at a 5-million-SWU-per-year capacity, was expected in 1978. Brazil and West Germany planned to build a 180,000-SWU-per-year demonstration enrichment plant in Brazil using an advanced nozzle enrichment method. A large-scale commercial plant with a capacity of 1 to 2 million SWU per year was to follow viability studies.

Progress continued toward solving problems in the backend of the fuel cycle. Research programs dealing with spent fuel storage, reprocessing, and waste management continued in those countries having large nuclear programs.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Australia, Brazil, Czechoslovakia, Finland, East Germany, West Germany, Hungary, India, Israel, Japan, the People's Republic of China, and the U.S.S.R. are believed to have produced uranium oxide, but information is inadequate to make reliable estimates of output levels.

[2] Data represent shipments. Official production for 1975 was reported at 4,631 short tons.

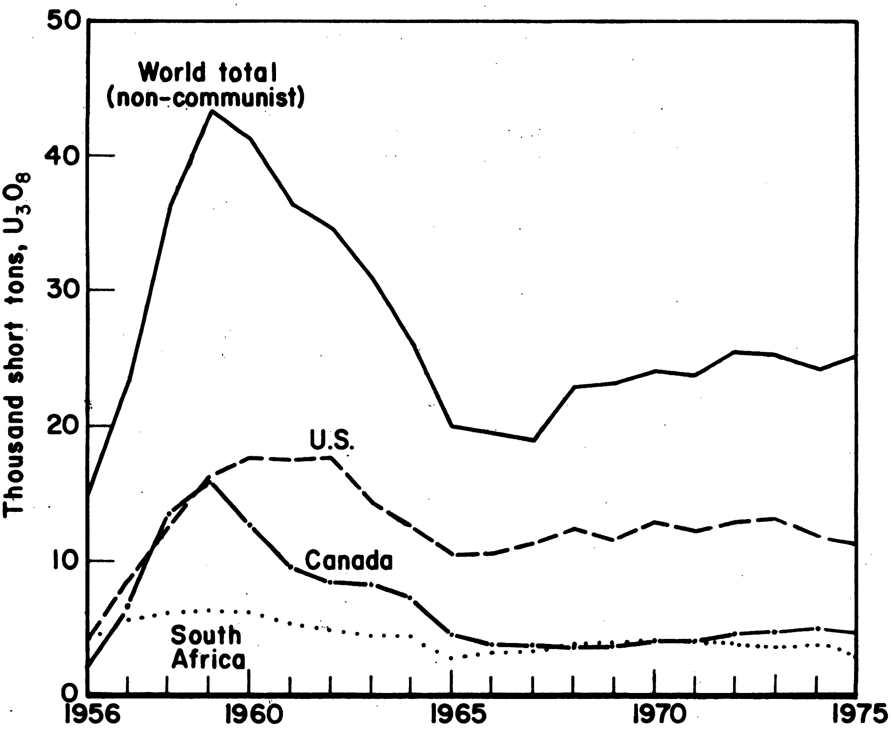

Figure 2.—World production of uranium concentrate (U_3O_8).

Australia.—As of June 30, 1975, Australia's reasonably assured uranium reserves recoverable at less than $10 per pound of U_3O_8 totaled 202,000 tons.[29] This was an increase of about 60,000 tons of U_3O_8 over that estimated in June 1974. Known uranium reserves recoverable at less than $30 per pound of U_3O_8 were estimated at 333,000 tons.[30] The reserves of the various deposits were as follows:

Location	Deposit	Reserves (tons of U_3O_8)
Northern Territory	Ranger	111,000
Do	Nabarlek	10,000
Do	Koongarra	20,000
Do	Jabiluka	115,000
Queensland	Mary Kathleen	10,000
South Australia	Lake Frome	17,000
Western Australia	Yeelirree	50,000
Total		333,000

During much of 1975, the Government's uranium policy continued to delay development of the country's uranium deposits. This policy specified Government ownership of deposits and Government-industry partnerships in the Northern Territory; permitted only the Government, through the Australian Atomic Energy Commission

---

[29] Australian Atomic Energy Commission. Twenty-third Annual Report. Year ending June 30, 1975.

[30] Western Mining Corp. Ltd. The Australian Uranium Mining Industry. September 1975, 22 pp.

(AAEC), to undertake uranium exploration in certain areas; and allowed no new contracts for uranium sales or new foreign participation. A new Government elected in December was expected to extensively modify this program in 1976. The new Government indicated that it intended to phase the AAEC out of exploration and to allow companies to be relatively free to develop deposits and to negotiate sales contracts. The Government, however, planned to continue to be involved in the industry and indicated that a minimum of 75% Australian ownership in deposits was expected.

Mary Kathleen Uranium Ltd. (MKU) was recommissioning its mine and mill near Mount Isa at a cost of $26 million, preparing for commercial operation in mid-1976.[31] MKU planned production at a rate of 1,000 tons of U_3O_8 per year to fulfill export contract obligations of 5,000 tons of U_3O_8 by 1982. The Mary Kathleen mine was expected to be Australia's only uranium producer for the next 3 to 5 years.

The status of 6,530 tons of U_3O_8 contracted for export by other Australian companies for the period 1977 through 1986 awaited further legislative action; however, the Government planned to honor these contracts from stocks, if necessary.

Brazil.—The Brazilian Government planned to spend more than $500 million on its nuclear program between 1975 and 1979, and a total of $10 billion by 1990 to reduce the country's dependence on energy imports. In June, Brazil signed a 15-year, $4.5 billion agreement with West Germany that will provide uranium reactor and fuel technology. Under terms of the agreement, Brazil will buy eight 1,300-megawatt nuclear powerplants. Several joint German-Brazilian companies were to be established for fuel manufacture and reprocessing, enrichment, and exploration and mining.[32]

The Brazilian state agency Comissão Nacional de Energia Nuclear (CNEN) spent about $17 million in 1975 on uranium prospecting and planned to spend about $20 million in 1976. Measured reserves were about 10,000 tons of U_3O_8 at yearend 1975.

Canada.—Uranium production, about 4,600 tons of U_3O_8 in 1975, was slightly lower than that in 1974 due mainly to shortages of mine labor and the processing of lower grade ores.[33] Exploration activity, however, continued to increase, and significant mineralization was found in several areas, most notably at Key Lake in Saskatchewan. All uranium producers were in the process of expanding facilities. Several new and rehabilitated mines were expected to come onstream in the near future.

According to revised estimates of the Canadian Department of Energy, Mines, and Resources, recoverable uranium reserves to $40 per pound of U_3O_8 totaled 562,000 tons, an increase of 7.8% over those of 1974.[34] A comparison between the 1975 and 1974 (in parentheses) uranium reserve assessment in thousand tons, follows:

Minable, price per pound [1]	Measured	Indicated	Inferred
0–$20	82 (77)	107 (107)	226 (237)
$20–$40	14 (4)	22 (17)	111 (84)
Total	96 (81)	129 (124)	337 (321)

[1] Figures in parentheses are from the 1974 assessment using price categories of up to $15 per pound of U_3O_8 and $15 to $30 per pound of U_3O_8.

In addition to the aforementioned uranium reserve assessment, 450,000 tons of U_3O_8 was estimated to be in potential resources.

Canada's national uranium policy enacted late in 1974 requires at least a 30-year reserve of nuclear fuel for existing, committed, and planned reactors in any 10-year forward period. Allocations, amounting to 21% of each producer's reserves, were applied to provide for the 30-year fueling requirements of 81,000 tons of U_3O_8 for the 14,700 megawatts nuclear capacity expected to be operating in Canada by 1986. The uranium producers had export commitments of about 110,000 tons of U_3O_8 and domestic commitments of 33,000 tons of U_3O_8 at the end of 1975. Production was expected to increase significantly in the next 10 years to meet contract commitments and anticipated demand for uranium. Government estimates of Canadian uranium production to 1985 were as follows:

[34] Energy, Mines, and Resources Canada. 1975 Assessment of Canada's Uranium Supply and Demand. June 1976, 14 pp.

Year	Tons of U_3O_8
1976	7,600
1977	8,800
1978	10,400
1979	11,600
1980	13,000
1981	13,400
1982	14,400
1983	13,500
1984	15,000
1985	15,000

In 1975, four producers, Denison Mines Ltd., Rio Algom Ltd., Eldorado Nuclear Ltd. (ENL), and Gulf Minerals Canada Ltd. (GMC), produced a total of 4,631 tons of U_3O_8. Shipments were higher, totaling 6,136 tons of U_3O_8. Denison had nearly completed expansion of its mill capacity to 7,100 tons of ore per day by yearend 1975.[35] Rio Algom began a $76 million mine-mill expansion in April.[36] The capacity of the Quirke mill was to be increased from 4,500 tons of ore daily to 7,000 tons by 1978. Three new mine levels were being developed, and shafts at the Milliken and Lacnor mines were being enlarged to increase hoisting capacity.

ENL continued a $15 million program to expand its production rate to 1,000 tons per year of U_3O_8 by 1979. The company was expanding its mill, planning to develop several small open pits, increasing production of the Fay mine, and reopening the Verna mine that closed in 1969.[37] By yearend 1975, the Rabbit Lake open pit operation of GMC, in partnership with Uranerz Canada Ltd., was producing ore. The mill, which has a rated production capacity of 2,000 tons of ore per day or 2,250 tons of U_3O_8 per year, was expected to be fully operational in 1976.

Madawaska Mines Ltd., a joint venture of Federal Resources Ltd. (51%) and Consolidated Canadian Faraday Ltd. (49%), was reopening the Faraday mine and mill, and expected to begin ore production at a rate of 1,500 tons daily by July 1976.[38] Amok Ltd., owned entirely by French interests (Compagnie de Mokta, Cie. Française des Minerais d'Uranium, Péchiney Ugine Kuhlmann, and Commissariat à l'Energie Atomique), planned to bring its Cluff Lake deposit in northern Saskatchewan into production in 1977. An initial milling rate of 200 tons per day was scheduled, followed by a second phase mill with a milling rate of 1,000 to 2,000 tons per day by the late 1980's. Agnew Lake Mines Ltd. continued a $3 million program, begun in 1974, to test large-scale leaching of uranium from broken ore both on surface and underground. The mine, near Espanola, Ontario, was dewatered, and underground development was in progress.

Central African Republic.—In June, the Government, with the Commissariat à l'Energie Atomique (CEA) and Swiss Aluminium Ltd., established Société d'Uranium Centrafricain (URCA) to exploit the uranium deposits at Bakouma.[39] These deposits reportedly contain about 25,000 tons of U_3O_8. Design and construction of a mill was planned after pilot plant testing of the ore in France.

France.—The Government discontinued plans to develop boiling water reactors (BWR), and indicated that all future additions will be pressure water reactors (PWR) of Westinghouse design. In a move to reduce Westinghouse Electric Corp.'s (WEC) share of the French nuclear reactor industry, CEA arranged to obtain 67% of WEC's 45% share of Société Franco-Americain de Conservation Atomiques (Framatome). In 1982, Creusot-Loire, 51% owner of Framatome, was to receive WEC's remaining 15% of the company.

France's prototype fast breeder, the 250-megawatt Phénix, continued to operate successfully at very high load factors. Nucleaire Europeene à Neutrons Rapides S.A., a multinational utility created jointly by France (51%), Italy (33%), and West Germany (16%), planned to order in 1976 a commercial-sized 1,200-megawatt, Super-Phénix. The proposed site for the

[39] U.S. Embassy, Bangui, Central African Republic. State Department Airgram A-008, Mar. 1, 1976, pp. 2–3.

Super-Phénix was at Creys-Malville, France.

India.—In September, the Uranium Corp. of India, Ltd. (UCI), began recovering uranium from copper tailings from the India Copper Corp. mine at Surda.[40] About 400 tons of copper tailings per day was processed in the plant using 20 wet concentrating tables. The lean uranium values in the feed assaying about 0.015% U_3O_8 were upgraded to about 0.12% U_3O_8 at a recovery of 50%. The wet mineral concentrates were transported to UCI's mill at Jaduguda for further processing.

Italy.—AGIP Mineraria purchased a uranium deposit near Novazza and planned to develop the deposit after further exploration.[41] The deposit reportedly contains 1.65 million tons of ore containing 1,650 tons of U_3O_8.

Niger.—In 1975, Niger ranked fifth in the world in both uranium production and in known reserves of uranium ore at $10 per pound of U_3O_8. Production was 1,820 tons of U_3O_8 in 1975 compared with 1,430 tons in 1974. The Arlit mine of Société des Mines de L'Air (SOMAIR), an international consortium composed of Nigerien, French, Italian, and West German interests, was the only uranium producer in 1975. One new mine was under development at Akouta, 5 miles southwest of Arlit, and another at Imouraren, about 50 miles south of Arlit, was being evaluated for possible development. The Government projected that uranium production would increase to 3,300 tons of U_3O_8 by 1978, 4,700 tons of U_3O_8 by 1980, and about 9,500 tons of U_3O_8 by 1985.

In 1975, SOMAIR increased the annual capacity of the Arlit mill to 1,800 tons of U_3O_8 at a cost of about $20 million and scheduled an additional capacity increase of 200 tons of U_3O_8 for completion in 1977.

In June, Compagnie Minière D'Akouta (COMINAK), a consortium composed of Nigerien, French, Spanish, and Japanese companies, began underground development of its Akouta mine. COMINAK planned to achieve a production rate of about 2,000 tons of U_3O_8 per year, beginning in 1978. Reserves, which average about 0.45% U_3O_8 were sufficient for at least 15 years at the scheduled rate of production.

South Africa, Republic of.—Uranium output, as a byproduct and coproduct at seven gold mines, was 292 tons of U_3O_8 lower than that of 1974, owing to the processing of lower grade gold tailings. The uranium content in ore processed decreased from 0.454 pounds of U_3O_8 per ton in 1974, to 0.417 pounds per ton in 1975. Production in 1975, by mine, was as follows:

Mine	Pounds of U_3O_8
Blyvooruitzicht	333,498
Buffelfontein	1,316,820
Harmony	938,500
Hartebeestfontein	913,308
Vaal Reefs	2,051,423
West Driefontein	331,888
Western Deep Levels	318,426
Total	6,198,858

Thirteen gold mines were considered capable of supporting uranium production, and 11 mines had uranium extraction plants. Several uranium mills were being rehabilitated to process uranium-rich gold tailings which continued to be stockpiled.

South-West Africa, Territory of.—Open pit development and mill construction continued on schedule at the Rossing deposit. The initial production rate, 60,000 tons of ore per day and 15 million pounds of U_3O_8 per year, will make the mine the world's largest uranium producer. Future plans called for the ore production rate to be increased to 120,000 tons per day. Initial production was scheduled for late 1976.

Spain.—The Government's Empress Nacional del Uranio, S.A. (ENUSA), scheduled an extensive program to increase production of uranium in the next few years to help meet the country's requirements for nuclear fuel. A 140-ton-per-year uranium mill at Ciudad Rodrigo, Salamanca, was commissioned in 1975, raising Spain's annual production capacity to 220 tons of U_3O_8. By 1978, a new conventional acid leaching-solvent extraction mill, having an annual capacity of 600 tons per year of U_3O_8, was also planned at Ciudad Rodrigo. ENUSA was also scheduled to build a facility in southern Spain to recover about 140 tons of U_3O_8 per year from phosphoric acid production.

[41] U.S. Embassy, Rome, Italy. Italian Energy Finds. State Department Airgram A-214, May 12, 1975, 2 pp.

Yugoslavia.—Development continued on a uranium deposit near Zirovski Vrh, Slovenia. Reserves were considered adequate to support production of 300 tons of U_3O_8 per year for a period of 15 years. Production was expected by 1978.

TECHNOLOGY

ERDA-sponsored projects to aid uranium exploration and assessment continued. In August, a systematic reconnaissance survey of the country's surface waters, groundwaters, and stream sediments was begun for the purpose of determining the role of uranium and its pathfinders as guides for uranium search.[42] The systematic sampling of the nation's streams was expected to provide evidence of uranium occurrences not previously known. Detection capabilities of LANDSAT multispectral scanner data for use in the search for roll-type uranium deposits were studied.[43] It was found that an image based on a single-ratio technique was adequate to separate hematite haloes near uranium deposits.

Measurement of radioactive bismuth (bismuth-214) in the atmosphere was investigated to improve data obtained during airborne gamma-ray surveys.[44] A low-cost system to explore for uranium deposits under bodies of water was developed in Canada.[45] The survey determines lake bottom topography, delineates outcrop areas, and outlines radiometric anomalies.

Other methods to explore for uranium included: Determination of radium in soil samples,[46] measurement of the relative heat flux between sample points in shallow boreholes,[47] and measurement of delayed fission neutrons in formations.[48] Sandia Laboratories, supported by ERDA, was conducting a feasibility study to determine uranium content in rocks intersected in drillholes. The system employs a pulsed neutron generator which provides neutrons which collide with and split the nuclei of uranium atoms. Neutrons resulting from fissioning are counted to indicate the uranium content.

A comparative study of the geostatistical ore reserve estimation method versus conventional methods using real data from an operating mine illustrated the practicality of the geostatistical method in certain types of uranium ore reserve estimation.[49] The Bureau of Mines studied the Chattanooga Shale to determine the quantity and quality of the uranium resources present and to assess specific environmental effects of mining the shale.[50] The study concluded that the uranium resources are large and could be extracted by known mining and processing technology; however, production, under present conditions, would not be economic and the environmental impact in the production area would be extensive.

Increasing demand and high uranium prices continued to stimulate the industry's interest in in situ leaching or solution mining as a means to reduce investment and construction lead time and to produce from low-grade ore bodies.[51] Methods of petroleum recovery technology were being applied to determine the amenability of uranium-bearing deposits to solution mining. The action of a biological agent such as Thiobacillus or Ferrobacillus in situ reportedly increases the concentration of weak sulfuric acid leach solution, thereby improving the uranium recovery.[52]

[51] Chemical Week. New Solution Cuts Uranium Mining Costs. V. 117, No. 26, Dec. 24, 1975, pp. 28–29.

The Bureau of Mines expanded its research and development work on processing technology for recovery of uranium from low grade and refractory ores. Acid-leach extraction of uranium from refractory carboniferous ores, normally resistant to conventional acid leaching, was successful after the ores were subjected to autoclave oxidation or to roasting. Uranium recoveries of up to 93% were reported.

The United Kingdom Atomic Energy Authority developed a new method, known as the ferric leach bacterial regeneration system, to leach uranium from relatively coarse mill-grade ore using acidic ferric sulfate. The bacteria, thiobacillus ferrooxidans, was introduced to convert the leach reaction product ferrous sulfate back to ferric sulfate, which is recycled.

Two process developments resulting in reducing costs 20% to 30% by eliminating steps in the production of UF_6 were described in 1975.[53] A Japanese process developed by Power Reactor and Nuclear Development Corp. and Asahi Chemical Industry Corp., purifies uranium in conventional sulfuric acid leach solution by solvent extraction, followed by stripping with chloride solution. The uranium is put in the uranous state by electrolytic reduction in a cation exchange membrane cell, then precipitated with HF as insoluble UF_4 "green cake." A French process is similar, although in one approach, the uranium in the chloride stage can be chemically reduced with SO_2 in the presence of copper and HF to form "green cake." Both processes produce, in an ore processing plant, a product suitable for direct fluorination to UF_6.

Progress was reported in isotopic enrichment of U^{235} by laser beam in the laboratory. Tests indicated higher separation factors than from other enrichment methods, suggesting that laser methods, if commercially successful, would reduce enrichment plant investment and operating costs.[54] Laser enrichment techniques were based on the selective excitation of U^{235} by tunable lasers followed by chemical separation or by electrical or mechanical separation. Four fundamental requirements were necessary to achieve enrichment: An absorption spectrum in which different isotopes absorb radiation at different wavelengths; a laser that can deliver a very narrow band of radiation so that only one isotope will absorb it; a chemical or physical process that can separate the excited atoms; and atoms that remain excited long enough to achieve separation.[55]

The NRC continued efforts to improve light water reactor (LWR) safety. Research was directed toward developing methods of calculating the course of events if an accident should occur. To assist this effort, NRC conducted tests at the Power Burst Facility (PBF) at the Idaho National Engineering Laboratory to provide data to define the behavior of nuclear fuels under abnormal and hypothetical accident conditions. The Loss-of-Fluid-Test Program (LOFT), NRC's largest experimental facility, was nearing completion and the first experiments were expected in 1976. The LOFT facility was designed to provide verification for analytical methods for prediction of integrated system behavior in a loss-of-coolant accident.

The Ministry of International Trade and Industry (MITI) in Japan planned to conduct a 10-year construction and trials program to test nuclear reactor safety during earthquakes.[56] A $70 million, shaking-table facility, funded by MITI and Japan's nuclear industry, was to be built to test power reactors weighing up to 1,100 tons.

ERDA continued its basic research and development program on four breeder concepts—the liquid metal, fast breeder reactor (LMFBR), the light water breeder, the gas-cooled breeder, and the molten salt breeder. Reference designs, work schedules, and cost data were established for the demonstration Clinch River LMFBR in Tennessee. ERDA planned to have the facility completed in 1983. The Fast Flux Test Facility for testing breeder fuels and materials, and for safety and reactor development experience, was expected to be completed in 1977. Progress was made in studies on advanced oxide fuels and higher breeding mixed uranium-plutonium carbide and nitride fuels.

Vanadium

By Grace N. Broderick [1]

Consumption of vanadium in 1975 in the United States showed a decrease of 24% from the alltime high of 1974. This decrease resulted from a decline in steel demand, reduced activity in aircraft construction, and less use of vanadium by the chemical industry. U.S. production of vanadium oxide also was lower in 1975, decreasing by 9%. U.S. price quotations for the principal vanadium materials, which rose appreciably in 1974, remained stable in 1975. Both exports and imports of ferrovanadium were down in 1975. Exports classified as ores, concentrates, oxides, and vanadates increased over those of 1974. Vanadium pentoxide imports, which until 1974 were insignificant, accounted for about one-third of total vanadium imports for consumption in 1975.

Table 1.—Salient vanadium statistics

r Revised.

[1] Recoverable vanadium contained in uranium and vanadium ores and concentrates received at mills, plus vanadium recovered from ferrophosphorus derived from domestic phosphate rock.

[2] Produced directly from all domestic sources, and includes metavanadates; in 1971 also includes small byproduct quantities from imported chromium ores.

[3] Less than ½ unit.

Legislation and Government Programs.—As of December 31, 1975, deliveries of previously sold material had reduced the physical inventory of the U.S. Government stockpile to 540 tons of vanadium, all in the form of vanadium pentoxide. This uncommitted excess cannot be sold until Congressional authorization is obtained.

---

[1] Physical scientist, Division of Ferrous Metals.

DOMESTIC PRODUCTION

Domestic production of vanadium was somewhat lower than that in 1974. The quantity recovered from uranium-vanadium ores of the Colorado Plateau increased in 1975 and exceeded the quantity recovered from Arkansas vanadium ore, which declined from that of the previous year. On a State basis, however, Arkansas retained its position as the principal vanadium producer. The amount of vanadium recovered from ferrophosphorus continued to decline. Some mills also processed fly ash, oil residues, spent catalysts, and foreign vanadium-bearing slags. Vanadium obtained by processing imported vanadium-bearing materials was not included in any of the production figures shown in the tables nor was the vanadium recovered directly from slags or residues as ferrovanadium or similar products.

Union Carbide Corp. continued to operate both its Uravan-Rifle mill complex in Colorado, and its Hot Springs, Ark., mill. The Soda Springs, Idaho, plant of Kerr-McGee Corp. and the Hot Springs, Ark., plant of Union Carbide Corp. produced all the vanadium that was recovered from byproduct ferrophosphorus. By yearend, Atlas Corp. had nearly completed installation of the vanadium recovery circuit at its Moab, Utah, plant.

Producers of vanadium addition agents for use in the production of steel and titanium alloys included Engelhard Minerals & Chemicals Corp.; Foote Mineral Co; Reading Alloys, Inc.; Shieldalloy Corp. (a Division of Metallurg, Inc.); and Union Carbide Corp.

Table 2.—Mine production and recoverable vanadium of domestic origin produced in the United States

(Short tons of contained vanadium)

Year	Mine production [1]	Recoverable vanadium [2]
1971	5,547	5,252
1972	4,699	4,887
1973	4,117	4,877
1974	5,240	4,870
1975	5,213	4,743

[1] Measured by receipts of uranium and vanadium ores and concentrates at mills, vanadium content.

[2] Recoverable vanadium contained in uranium and vanadium ores and concentrates received at mills, plus vanadium recovered from ferrophosphorus derived from domestic phosphate rock.

Table 3.—Production of vanadium oxides in the United States [1]

(Short tons)

Year	Gross weight	Oxide content [2]
1971	10,492	9,448
1972	10,410	9,367
1973	8,226	8,688
1974	9,804	9,588
1975	8,597	8,674

[1] Produced directly from all domestic sources including domestic residues. Includes metavanadates; in 1971, includes small byproduct quantities from imported chromium ores, also.

[2] Expressed as equivalent V_2O_5.

Plans to construct a ferroalloy plant at Pulaski, Pa., to produce ferrovanadium and other alloys were announced by The Pesses Co. The plant, which is expected to be in operation by late 1976, is not expected to produce ferrovanadium until 1977 or 1978, when an arc furnace will be installed.

CONSUMPTION AND USES

Domestic consumption of vanadium by type of material and by end-use category decreased about 24% in 1975 from the alltime high of 7,200 tons set in 1974. Decreases occurred in all end-use categories except carbon steel, cast irons, and welding and alloy hard-facing rods and materials. Eighty-five percent of the vanadium was consumed as ferrovanadium and associated proprietary vanadium-iron-carbon materials. A decline in steel demand, reduced activity in aircraft construction, and less use of vanadium by the chemical industry were responsible for the decreased consumption.

Table 4.—Consumption and consumer stocks of vanadium materials in the United States
(Short tons of contained vanadium)

Type of material	1974		1975	
	Consumption	Ending stocks	Consumption	Ending stocks
Ferrovanadium [1]	6,076	1,732	4,703	868
Oxide	218	83	216	56

[2] Includes pigments.

STOCKS

In addition to the consumers' stocks shown in table 4, producers' stocks of vanadium as fused oxide, precipitated oxide, metavanadate, metal, alloys, and chemicals totaled 3,375 tons of contained vanadium at yearend 1975, compared with 1,920 tons at yearend 1974.

PRICES

Prices in the United States for the principal vanadium materials were stable throughout 1975. The price for domestic 98% fused vanadium pentoxide, as quoted by Metals Week, continued as a dual quotation of $2.45 and $3.06 per pound of contained V_2O_5 for the entire year. Prices for technical-grade, air-dried vanadium pentoxide remained at $2.98 and $3.06 per pound of contained V_2O_5 in 1975.

The price for U.S. standard grade ferrovanadium remained at $6.35 per pound of contained vanadium, and the price of Carvan and Ferovan remained at $5.10 per pound of contained vanadium during the year.

FOREIGN TRADE

Exports of ferrovanadium were down about 24% in 1975 but exports of vanadium ores, concentrates, and oxides rose 6% over those of the previous year. The average declared value for exports of ores, concentrates, and technical-grade oxides was $2.12 per pound of contained vanadium pentoxide in 1975, compared with $1.83 per pound in 1974. The average declared value for exports of ferrovanadium in 1975 was $3.91 per pound of alloy, compared with $2.94 in 1974.

Ferrovanadium imports declined in quantity but increased in value. No imports classified as vanadium ore and concentrate were received in 1975. Imports of vanadium-bearing residues, such as ashes and slags, totaled 5.8 million pounds of contained vanadium in 1975, compared with 5.0 million pounds of contained vanadium in 1974. Most of this material continued to come from the Republic of South Africa, the U.S.S.R., and Chile.

Imports for consumption of vanadium pentoxide (anhydride) totaled 4,297,303 pounds valued at $7,873,796, compared with 1,904,182 pounds valued at $2,931,329 in 1974.

Tariffs.—Imports of vanadium pentoxide (anhydride) are presently designated as TSUSA 422.60 in the Tariff Schedules of the United States (Annotated). They are dutiable at 16% ad valorem for favored nations; the statutory rate is 40% ad valorem.

WORLD REVIEW

In addition to the nations listed in table 9, some others had relatively small vanadium production from secondary, waste, or byproduct sources. Japan and West Germany produced vanadium from several such sources.

Australia.—The Barrambie project of Ferrovanadium Corp. N.L. was reportedly approaching the pilot plant stage.[2] This project would lead to the exploitation of a large vanadium-titanium-iron deposit, the initial discovery of which was made in 1960 as the result of an airborne survey. Since 1971, drilling of the area and other geophysical and geological work has been undertaken. Indicated ore reserves are put at some 30 million tons of ore containing an average of 0.7% V_2O_5, 15% TiO_2, and 26% Fe, while inferred reserves of unspecified grade are estimated at some 448 million tons.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] The Republic of South Africa officially reported the undistributed total production of vanadium in pentoxides and vanadate products as well as in vanadium bearing slags. Data on vanadium content of vanadium slag is estimated on the basis of a reported tonnage of vanadium-bearing slag (gross weight) multiplied by an assumed grade of 14% vanadium. Vanadium content of pentoxide and vanadate products represents the difference between the reported total and the calculated estimate for vanadium in slag.

[2] Data represent output of South West Africa Co. Ltd. for years ending June 30 of that stated.

Canada.—Research on a metallurgical process that would permit the recovery of some of the elements contained in the Magpie deposits, located about 80 miles north of Mingana, Quebec, was conducted by the Quebec Department of Natural Resources and the Canada Centre for Mineral and Energy Technology (CANMET), Department of Energy, Mines and Resources. These deposits contain more than 1 billion tons of titaniferous magnetite grading 43% Fe, 10.5% TiO_2, 1.6% Cr, and small amounts of vanadium, nickel, and aluminum. The Quebec Department of Natural Resources also was working on an ilmenite-magnetite deposit located in the Lac Doré area of Chibougamau, Quebec, that contains 1.3% vanadium.[3]

The principal consumers of vanadium in Canada are The Algoma Steel Corp., Ltd.; Atlas Steels Co. Division of Rio Algom Mines Ltd.; Burlington Steel Division of Slater Steel Industries Ltd.; Sydney Steel Corp. (Sysco); Dominion Foundries & Steel, Ltd. (Dofasco); Sidbec-Dosco Ltd.; Manitoba Rolling Mills Division of Dominion Bridge Co. Ltd.; The Steel Co. of Canada, Ltd (Stelco); and Colt Industries (Canada) Ltd.[3]

Finland.—According to Finnish trade statistics, Finland exported 2,955 tons of vanadium compounds[4] in 1974, compared with 2,594 tons in 1973. Of the 2,955 tons, 714 tons went to Sweden, 638 tons to West Germany, 623 tons to France, 331 tons to the U.S.S.R., 307 tons to Great Britain, 120 tons to Czechoslovakia, 89 tons to Brazil, 55 tons to Canada, 44 tons to Iceland, 30 tons to the U.S.A., and 1.7 tons each to Austria and Italy.

Rautaruukki Oy reported an output of 2,509 tons (gross weight) of vanadium pentoxide in 1975, compared with 2,918 tons (gross weight) in 1974.

Germany, West.—According to official trade statistics, West Germany imported 29,674 tons (gross weight) of vanadium-containing ashes, residues, and slag in 1975, compared with 32,848 tons (gross weight) in 1974.

India.—Vanadium was reported[5] as having been extracted on an industrial scale from local ores using a process developed by the National Metallurgical Laboratory and the State-owned Mysore Iron & Steel Ltd. The vanadiferous ore lies near Masanikeri, some 40 miles from the Mysore Iron & Steel works at Bhadravati.

Italy.—Italsider S.p.A. has adopted a vanadium-columbium steel (yield strength 70,000 pounds per square inch) for the production of pipe of 48 inches and 56 inches in diameter, with wall thicknesses up to 15 millimeters. The steel was developed in conjunction with the Vanadium International Technical Committee (Vanitec). The first experimental pipes were made by Italsider at its Taranto Works in December 1974, and commercial production began early in 1975 after further developmental studies. Over 150,000 tons of pipe had been produced by mid-July. In addition to its strength, the steel reportedly met the severe requirements for weldability and resistance to brittle fracture that are prescribed for Arctic pipeline construction.[6]

[4] Although the title of the export class is "vanadium compounds," the material is almost all vanadium pentoxide.

[5] Metal Bulletin (London). Indian V Success. No. 6018, Aug. 22, 1975, p. 40.

South Africa, Republic of.—South Africa, the world's leading vanadium-producing country, increased its output in 1975. Statistics, as published by the South African Government's Department of Mines, are for the combined forms—slag, polyvanadate and metavanadate and fused pentoxide as V_2O_5. In this combined form, production in 1975 totaled 20,946 tons, compared with 16,049 tons in 1974 and 16,149 tons in 1973.

During the fiscal year ending June 30, 1975, Highveld Steel and Vanadium Corp., Ltd. (HSV), South Africa's and the world's leading producer of vanadium, produced at its Witbank plant a total of 45,955 tons (gross weight) of vanadium-bearing slag, compared with 38,053 tons (gross weight) in the previous fiscal year; the company's Vantra Division produced fused vanadium pentoxide. A new primary crushing and washing section was installed[7] at HSV's Mapochs mine (near Roossenekal) to facilitate the handling of run-of-mine ore of a higher clay content than that formerly mined and to meet the higher tonnage called for by the corporation's Witbank works. Capacity of the ore treatment plant was increased from 300 to 475 tons per hour.

South Africa's second most important producer of vanadium, Ucar Minerals Corp. (wholly-owned subsidiary of Union Carbide Corp.), continued to produce vanadium pentoxide at Bon Accord near Pretoria from ore obtained from the Brits area.

A third producer, Transvaal Alloys Ltd., that began production of vanadium pentoxide in 1974 will expand its operations within a 5-year period if export sales (largely to Japan's Taiyo Koko K.K. and to West Germany) improve as envisaged in 1975.

Thermometallurgical Corp., (Pty) Ltd., produced ferroalloys, including ferrovanadium, at its Benoni plant. A total capacity of up to 1,200 tons per year for all alloys was reported[8] for this plant.

South-West Africa (International Territory).—The South West Africa Co., Ltd. (Swaco), continued to produce lead vanadate concentrate from the Berg Aukas mine, near Grootfontein. During the fiscal year ending June 30, 1975, the grade of the ore mined and hoisted was adversely affected by a decrease in the quantity of vanadium-rich cavity-fill material available for treatment. Production dropped 31% from 9,202 tons of lead vanadate concentrate in fiscal year 1974 to 6,361 tons in fiscal year 1975. On June 30th, 1975, about 1,323 tons of lead vanadate concentrate was held in the pipeline between the mine and the smelter in West Germany.

TECHNOLOGY

The Bureau of Mines published part 1 of a study on the use of nitride intermediates in the preparation of columbium, vanadium, and tantalum metals.[9] The objective of laboratory research at the Boulder City Metallurgy Research Laboratory reported in part 1 was to study the rate and degree of nitride conversion of the oxides of these metals with ammonia preparatory to use of the nitride to produce the respective metals; to optimize experimental conditions; and to obtain a nitride product as low as possible in oxygen in the shortest practical time. Variables examined included reactor material, temperature, space velocity and composition of the nitriding gases, and composition, particle size, and thermal treatment of the oxides. Most of the nitride conversion data reported were generated from single experiments. The best nitride conversions were obtained in nonmetal reactors.

Use of electrorefined vanadium metal prepared at the Bureau of Mines Boulder City Metallurgy Research Laboratory was documented in two publications. One study[10] investigated the change in electrical resistivity of interstitial alloys as a function of the static displacement caused by the interstitials. The other study[11] involved determining constitution diagrams of noble metal alloys, including vanadium-ruthenium and vanadium-rhenium.

Vanitec, which continued to sponsor research on vanadium applications, published the first of a series of monographs, "Vanadium Steel Reinforcing Bars." Since its formation in 1973, Vanitec has sponsored research programs on high-strength steels in the United Kingdom at the National Physical Laboratory and the Welding Institute, and in Italy with the Centro Sperimentale Metallurgico and Italsider S.p.A. The committee consists of representatives from the following major producers of vanadium ores, concentrates, alloys and other compounds: Awamura Metal Industry Ltd., Billiton Phibro B.V., BOC Murex, Continental Alloys S.A., Climax Molybdenum Co., Elkem Spigerverket A/S, Foote Mineral Co., Highveld Steel and Vanadium Corp., Metallurg, Inc., Nippon Denko KK, Rautaruukki Oy, Sadacem, Société Française d'Electrométallurgie (Sofrem), South West Africa Co., Taiyo Mining, Termoligas Metalurgicas S.A., Treibacher Chemische Werke AG, and Union Carbide Corp.

A method for recovering vanadium from certain iron ores without sodium or alkali contamination was developed and patented.[12] Vanadium-bearing iron ore is mixed with a calcium-bearing compound such as limestone; the mixture is roasted in an oxidizing atmosphere to form calcium vanadates, which are relatively insoluble in water but can be leached with an aqueous solution containing carbonate or bicarbonate compounds, preferably ammonium carbonate or bicarbonate. Use of ammonium compounds is reported to produce a sodium-free vanadium product. Other insoluble calcium compounds produced during roasting remain with the leached iron ore residue, which can be processed to recover the iron.

A patent was issued for extraction of vanadium values from vanadiferous slag from the manufacture of steel or iron from ores containing vanadium as an impurity. A mixture of slag and sodium carbonate was heated between 600° to 800° C in a convertor in the presence of oxygen to solubilize the vanadium, the reaction product leached with water, and the vanadium values recovered from the leach.[13]

Another patent covered a process for extraction of vanadium and titanium values from slag formed by smelting iron oxide which contains substantial percentages of vanadium and titanium. A mixture of slag and sodium chloride was heated between 1300° to 1700° C to form an altered slag. The altered slag was oxidized by salt-roasting in an oxidizing atmosphere to solubilize vanadium oxide in the plus-five valence state, the slag leached, and the leach solution processed for vanadium. Titanium was recovered from the low-vanadium residue by known methods.[14]

Vermiculite

By Richard H. Singleton [1]

Crude vermiculite output totaled 330,000 tons in 1975, a decline of 3% from that produced in 1974. World production of crude increased 4% in 1975 to approximately 577,000 tons. Domestic output of exfoliated vermiculite declined 15% to 235,000 tons. Vermiculite was exfoliated at 51 plants in 29 States using mainly domestic crude but also crude imported from the Republic of South Africa. Two exfoliation plants closed in 1975. Exfoliated vermiculite continued to be used mainly in the building industry as concrete aggregate, as premixes for acoustic, fireproofing, and other purposes, and as loose-fill and block insulation. Demand for these lightweight products continued to decrease in accord with a decline in building activity.

DOMESTIC PRODUCTION

Crude Vermiculite.—Output of vermiculite concentrate, commonly called crude, decreased from 341,000 tons in 1974 to 330,000 tons in 1975. Capacity of W. R. Grace & Co.'s beneficiation mill at Libby, Mont., was increased. W.R. Grace & Co. also continued to mine and beneficiate vermiculite near Enoree, S.C. In addition, Patterson Vermiculite Co. continued to produce a small tonnage at Lanford, S.C. Plans of W. R. Grace & Co. to develop vermiculite deposits near Louisa, Va., remained shelved during 1975, mainly as a result of zoning problems.

Exfoliated Vermiculite.—The tonnage of exfoliated vermiculite sold or used decreased 15% to 235,000 in 1975. Leading States, accounting for 42% of the exfoliated vermiculite sold or used, were California, Florida, New Jersey, South Carolina, and Texas. W. R. Grace & Co., Construction Products Div., the principal producer of crude vermiculite, operated 30 exfoliating plants in 24 States. Crude vermiculite imported from the Republic of South Africa was exfoliated in 11 domestic plants. The other 10 domestic exfoliating plants used domestic crude as feedstock. The sources of crude for domestic exfoliated vermiculite sold and used were Libby, Mont., 47%; South Carolina, 44%; and the Republic of South Africa, 9%.

CONSUMPTION AND USES

The use pattern for exfoliated vermiculite by main categories showed no major change from 1974 and was as follows: Aggregates, 50%; insulation, 31%; agriculture, 16%; and miscellaneous, 3%.

Demand for smaller flake sizes decreased. Almost no demand existed for flake sizes below 65 mesh.

An end use breakdown is shown in thousand tons in the following tabulation:

Use	1974	1975
Aggregates:		
Concrete	94	75
Plaster	5	4
Premixes[1]	42	38
Total	141	117
Insulation:		
Loose-fill	47	39
Block	32	35
Packing	1	--
Total	80	74
Agriculture:		
Horticulture and soil conditioning	40	31
Fertilizer carrier	7	7
Other	--	--
Total	47	38
Miscellaneous	6	6
Grand total	274	235

[1] Includes vermiculite used in premixes for acoustic and fireproofing purposes, decorative textures, moisture sealant, etc.

PRICES

According to the Bureau of Mines canvass, the average value of domestic crude vermiculite increased 40% over the 1974 value to $41.70 per ton. The average value of exfoliated vermiculite increased 38% to $154.66 in 1975. These values are f.o.b. mine or plant.

Engineering and Mining Journal quoted nominal yearend prices for crude vermiculite as follows: Per short ton, f.o.b. mine, domestic crude, $38 to $63; and c.i.f. Atlantic ports, the Republic of South Africa crude, $60 to $80.

FOREIGN TRADE

Approximately 33,000 tons of crude vermiculite was imported duty-free into the United States from the Republic of South Africa, a 21% decrease under that imported in 1974. A total of 45,123 tons of crude was exported from the United States to Canada, primarily from Libby, Mont., a 2% increase over that exported in 1974.

WORLD REVIEW

Canada.—A total of 61,307 tons of crude vermiculite was imported in 1975, mostly from Montana and some from the Republic of South Africa, a 24% increase over that imported in 1974. Grace Construction Materials Ltd. operated exfoliating plants in 1974 at St. Thomas and Ajax, Ontario; Winnipeg, Manitoba; and Vancouver, British Columbia. F. Hyde & Co., Ltd. and Vermiculite Insulating Ltd. operated exfoliating plants at Montreal, Quebec, and Lachine, Quebec, respectively. Northern Perlite and Vermiculite Ltd. began operation in 1974 of an exfoliation plant at St. Boniface, Manitoba. The use pattern in 1974 was loose insulation, 75%; insulating concrete, 4%; insulating plaster, 2%; agriculture, 8%; and miscellaneous, 11%.[2]

South Africa, Republic of.—Crude vermiculite production capacity in the Transvaal, Republic of South Africa, was increased significantly. Actual production of crude increased 14% in 1975 to 228,761 tons. Total exports of crude increased 24% in 1975 to 205,000 tons. Nearly one-quarter of these exports went to the United States and Canada, and most of the balance was sent to Western Europe.

Zinc

By V. Anthony Cammarota, Jr.,[1] and Ronald J. DeFilippo [1]

With the lowered rate of economic activity in 1975, slab zinc consumption, mine and smelter production, Government stockpile releases, and imports of ores and concentrates all declined. Consumption of slab zinc, at 925,330 tons, decreased 28% from that of 1974.

Mine production was 469,355 tons, down 6% from that of 1974. Tennessee, New York, and Missouri were the major producing States accounting for one-half of domestic mine production. The New Jersey Zinc Co. began shipping concentrate from its new Elmwood mine in central Tennessee in January. In east Tennessee, ASARCO Incorporated shut down the Mascot mill in October and brought its new Young mill onstream. The Ontario mine in Utah began production in May. Callahan Mining Corp. and The New Jersey Zinc Co., through a joint venture, began developing a zinc-copper deposit in north-central Virginia.

Smelter production of primary slab zinc was 438,051 tons, down 21% from that of 1974, continuing the decline of zinc smelter production since 1969. National Zinc Co. was constructing a new electrolytic zinc plant in Bartlesville, Okla. to replace the old horizontal retort plant scheduled for closing in May 1976. The smelter was designed for a capacity of 56,000 tons per year. The New Jersey Zinc Co. and Union Minière of Belgium formed a joint venture to build a 90,000-ton-per-year electrolytic smelter at Clarksville, Tenn., for completion in 1979. Another zinc plant being planned by ASARCO at Stephensport, Ky., was postponed indefinitely. The company closed its 53,000-ton-per-year smelter at Amarillo, Tex. in May thereby reducing U.S. zinc smelting capacity to 652,000 tons per year.

Producer and consumer stocks were 250,878 tons on January 1, and climbed to 269,455 tons in April, the highest level in recent years. However, as smelter production declined and demand increased later in the year, stocks fell to 182,928 tons by yearend.

General imports of zinc in ores and concentrates decreased 40% from those of 1974 to 144,987 tons, of which Canada supplied about two-thirds of the total. Other major suppliers were Honduras, Mexico, and Nicaragua. Imports for consumption, however, more than tripled to 428,544 tons. General imports and imports for consumption of slab zinc were 380,437 tons and 374,922 tons, respectively, representing decreases of almost one-third from those of 1974. Canada was the leading source of general metal imports by providing 48% of the total, followed by Spain, 7%; Australia, 6%; and Finland, 5%.

The General Services Administration (GSA) shipped 5,886 tons of zinc from the Government stockpile in 1975. The last three quarters of the year were declared closed by GSA because of a high producer stock balance. Shelf-item commitments of 2,014 tons made in 1974 were cancelled during the year. The total amount of zinc authorized for sale at yearend was 172,000 tons.

In spite of the falling demand for zinc, the price during the year remained virtually unchanged at about 39 cents per pound for Prime Western zinc. The average for the year was 38.96 cents per pound. One company raised its price by 2 cents per pound, but was forced to rescind the increase when the other producers remained firm. The European producer price decreased from 38.58 cents per pound in January to 35.77 cents per pound in December, partly as a result of declining exchange rates. Several foreign producers began quoting prices on the basis of the U.S. dollar rather than of the British pound sterling because of pricing problems associated with currency alinements.

---

[1] Physical scientist, Division of Nonferrous Metals.

On August 9, 1975, the President signed Public Law 94–89 suspending the duty on zinc ores, concentrates, and zinc-bearing materials until June 30, 1978.

Legislation and Government Programs.—On August 9, Public Law 94–89 went into effect which suspended the duty on imported zinc ores, concentrates, drosses, waste and scrap, and other zinc-bearing materials until June 30, 1978.

In the first quarter of 1975, GSA sold 1,950 tons of zinc to producers but closed the last three quarters to any sales of zinc from stockpile excesses. GSA cited the high statistical position of producer stocks and its policy of not disrupting private sector markets. After shipments of 5,886 tons in 1975, total inventory was 385,714 tons at yearend. The uncommitted inventory was 374,830 tons of zinc including 172,130 tons available for disposal, and 202,700 tons as the strategic stockpile objective. The other 10,884 tons was committed to various Government agencies.

On November 17, the Environmental Protection Agency (EPA) put into effect interim effluent limitations for ore mining and processing facilities. After application of the best practical control technology currently available, water discharges from zinc mines were limited to a maximum of 1.0 milligram of zinc per liter for any one day, not to exceed an average of 0.5 milligram per liter over a 30-day period. Mills were not to exceed discharges of 0.4 milligram of zinc per liter and 0.2 milligram of zinc per liter on the same time basis.[2]

The Administrator of EPA promulgated regulations prescribing emission standards for copper, lead, and zinc smelters on December 30. Emissions of sulfur dioxide contained in gases discharged from roasters and from any sintering machine which eliminates more than 10% of the sulfur initially contained in the zinc sulfide concentrates processed are limited to 0.065% by volume (650 parts per million) averaged over a 2-hour period.[3]

The National Institute for Occupational Safety and Health (NIOSH) transmitted new criteria for zinc oxide exposure to the Occupational Safety and Health Administration. The NIOSH standards recommended that workers in contact with zinc oxide should not be exposed to a concentration of more than 5 milligrams of zinc oxide per cubic meter of air averaged over a 40-hour work week. Levels of 15 milligrams per cubic meter were not to be exceeded for more than 15 minutes at a time.

The International Lead and Zinc Study Group (ILZSG) held its 19th session in Geneva, Switzerland, November 3–8, to review developments in lead and zinc, and to consider projections for 1976. In its review of new mine and smelter projects a substantial increase in world zinc smelter projects was indicated, but there were also deferrals of some projects due to economic conditions. Subjects proposed for study by ILZSG included costs of processing lead and zinc, environmental costs, trade in scrap, and the extent of governmental aid to companies producing lead and zinc.

DOMESTIC PRODUCTION

MINE PRODUCTION

U.S. mine production from 19 States was 469,355 tons, a 6% decrease from that of 1974. Significant production increases were noted in Illinois, Nevada, Utah, and Washington. The major producing States in order of rank were Tennessee, 18%; New York and Missouri, 16% each; Colorado, 10%; and Idaho, 9%. All these States, except Idaho, showed lower production than in 1974. States east of the Mississippi accounted for about one-half of total U.S. mine production.

Zinc ore accounted for 52% of the total zinc production followed by zinc-lead ore, 21%; lead ore, 16%; copper-zinc and copper-lead-zinc ores, 7%; and other ores, 4%.

Table 6 shows the 25 leading U.S. zinc mines, which accounted for 87% of the recoverable domestic zinc mined in 1975. The five leading mines accounted for 40% of the total U.S. mine production.

Although Tennessee zinc mine production dropped 3% from that of 1974, the State displaced New York as the leading zinc producer. Eight mines produced zinc, all from zinc ores. The New Jersey Zinc Co. and Union Minière, S.A., of Belgium, formed a 60/40 joint venture in September called the Jersey Minière Zinc Co. The property to be developed by the venture includes some 3,000 acres around and including the first Elmwood mine, and a 3,000-ton-per-day mill which began processing development ore in mid-1974. All ore was being brought to the surface for milling at the Elmwood No. 1 shaft. The No. 2 shaft, about ½ mile to the east, was being used for service purposes. About 3½ miles to the southwest, a third shaft was sunk, the No. 3 or Gordonsville mine, which was joined by an incline to intersect ore to the north. A 9,000-ton-per-day mill near the No. 3 shaft was in the planning stage for possible completion by 1979. The No. 4 shaft was being sunk 1.5 miles south of Carthage. The No. 5 shaft was in the planning stage. New Jersey Zinc was independently developing its Lost Creek and Beaver Creek zinc properties in Jefferson County.

In east Tennessee, ASARCO increased its milling capacity by 20% with the opening of its new mill at the Young mine in September. The 8,500-ton-per-day facility will service all of ASARCO's east Tennessee zinc mines and was designed to replace the 1913-vintage Mascot mill, which formerly served this function. The mill has minimum disposal problems because all of the limestone which composes the host rock is sold for agricultural purposes or construction aggregate through the wholly-owned subsidiary, American Limestone Co. In addition, all process water is recycled. The zinc concentrate is used mainly for the production of zinc oxide at ASARCO's own plants in Ohio and Illinois. At Copperhill, Cities Service Co. extended the main shaft at the Calloway mine by 2,000 feet permitting access to a new crusher at the 33d level. A room approximately in the shape of a 30-foot cube was constructed at this level to house the crusher, and eliminate bringing ore up to the 23d level where the old crusher was located. Cities Service produced 9,200 tons of zinc concentrate, up 44% from 1974 production.

Toho Zinc Co. Ltd. and Nichimen Co. Ltd. agreed to a joint zinc exploration venture with Dresser Industries, Inc. in Tennessee and Kentucky. The interest centered mainly on a 25,000-acre concession in middle Tennessee. Zinc values were reported as high as 6%. St. Joe Minerals Corp. was also outlining zinc mineralization in Kentucky and Tennessee. A program of zinc exploration in Kentucky was suspended at midyear by ASARCO.

Zinc production as a coproduct from eight lead mines in Missouri fell 19% from that of 1974.

Production of zinc decreased 18% in New York where St. Joe Minerals Corp. operated the Balmat and Edwards mines. The Balmat mine retained its position as the nation's largest zinc producer. The Hyatt mine was reactivated to supplement ore from the Edwards mine where an estimated 4 years of minable ore remained.

In Colorado zinc production from 12 mines was 48,460 tons, down slightly from that of 1974. Idarado Mining Co., 80.1% owned by Newmont Mining Co., treated 406,000 tons of ore grading 3.24% zinc, 2.28% lead, 0.63% copper, and 0.3 and 1.50 ounces of gold and silver per ton, respectively. Costs increased because of increases in employee wages and benefits, smelter charges, and haulage distance within the mine. Resurrection Mining Co., wholly owned by Newmont Mining Co., produced 17,620 tons of zinc from the Leadville mine, a 15% increase over the 1974 level.

Zinc mine production was reported from 25 mines in Idaho where production remained about the same as that of 1974. The Bunker Hill Co., a wholly-owned subsidiary of Gulf Resources and Chemical Corp., mined approximately the same amount of ore as in 1974 from the Bunker Hill mine. Proven and probable reserves of zinc from the lead-zinc ore dropped 6% to 107,828 tons. Zinc production from the lead-zinc ores of the Star-Morning unit, owned 30% by Hecla Mining Co. and 70% by Bunker Hill, was about 16,000 tons, down 6% from 1974 production. Ore grade averaged 5.64% zinc, 5.0% lead, and 2.49 ounces of silver per ton. Average zinc grade dropped from 6.04% zinc, but the lead grade rose from 4.77%. Several new stopes were developed, mostly in short ore shoots and auxiliary veins. Most of the lateral development was done at the 7,700-foot level, but the No. 4 shaft was deepened to below the 7,900-foot level. A new pumping system and rock burst monitor were installed. Proven and probable reserves of zinc were 54,600 tons, down 11% from those of 1974. Hecla's Lucky Friday mine produced 2,234 tons of zinc, up 14% from that of 1974. Ore grade was 1.29% zinc, 10.71% lead, and 14.96 ounces of silver per ton. Lateral openings on the 4,250-foot level were completed and stope preparation was 60% accomplished. The main shaft was extended to the 4,660-foot level. The company reported its ore reserves at 505,000 tons.

Intermountain Mineral Engineers, Inc. with 50% participation by U.S. Antimony Corp., was rehabilitating the Nabob, Sydney, and Little Pittsburg mines in the Pine Creek area of the Coeur d'Alene mining district. A refurbishing program was undertaken at the 250-ton-per-day Nabob mill, which began intermittent production in June and milled 2,297 tons of ore on a custom basis. Custom milling would continue until production from the three mines can feed the mill to capacity. Development of the mines included a 60-foot raise on the Nabob 300 level; rehabilitation of the Sydney 600 level to remove gob; and 393 feet of diamond drilling, 150 feet of drifting, and construction of a 40-foot raise on the Little Pittsburg 600 level. A total of 1,450 tons of development rock was milled during the year. Probable and proven ore reserves at the Little Pittsburg mine were estimated by Intermountain to be 58,492 tons grading 13.92% combined lead and zinc, and 1.28 ounces of gold per ton. Reserves at old mine workings were estimated at 54,200 tons grading 10% combined lead and zinc and 1 ounce of gold per ton.

Utah production of zinc from two mines was 19,640 tons, a 56% increase over that of 1974. Park City Ventures, a joint venture owned 60% by The Anaconda Company and 40% by ASARCO, started its 750-ton-per-day concentrator at its lead-zinc-silver Ontario mine in April. New mineralization was encountered at the No. 3 shaft, No. 6 winze, and the silver fissure area. The Tintic Division of Kennecott Copper Corp. stated that it mined 13,800 tons of zinc.

Production was reported from one mine in Virginia, where production dipped 12%. Piedmont Mineral Associates, a joint venture of Callahan Mining Corp. (49%) and The New Jersey Zinc. Co. (51%), placed its Cofer mine at Mineral, Va., in development status in the third quarter. This new zinc-copper mine would be joined by the reactivation of one or two other mines in the area with the ores to be concentrated at a common mill at the Cofer site. Full production was set for mid-1978.

In Washington, production from the State's six mines increased over that of 1974. The Washington Zinc unit of Callahan Mining Corp. in northern Stevens County was placed in development status. Callahan's partners in the joint venture are United States Borax and Chemical Corp. and Brinco Ltd., both subsidiaries of Rio Tinto-Zinc Corp. Ltd. The venture was an extension of the old Van Stone lead-zinc body operated as an open-pit mine by the former American Smelting and Refining Co.

In Maine, the Blue Hill joint venture, 60% owned by Kerr-Addison Mines, Ltd. and 40% by Kerramerican, Inc., was the only zinc producer in the State. Mine production of recoverable zinc was 8,318 tons, down 20% from that of 1974. Total ore mined was 211,210 tons grading 4.9% copper and 4.9% zinc. Because of zinc smelter cutbacks, 7,150 tons of concentrate was stockpiled. Minable ore reserves of 522,000 tons grading 3.4% zinc were down 52% from those of 1974. Drilling in the Carlton area, south of the current workings, indicated reserves of 1.4 million tons of ore grading 8.19% zinc at a level of 700 to 1,200 feet below the present workings, but development was not contemplated.

Mine production of zinc from 3 mines in Wisconsin showed little change from that of 1974. Noranda Mines Ltd. announced the discovery of a copper-zinc massive sulfide deposit southeast of Rhinelander.

Arizona zinc production from seven mines was 8,655 tons, down 11% from that of 1974. Cyprus Mines Corp. produced 94,600 tons of ore grading 12.5% zinc and 3.73% copper from its Cyprus Bruce mine. Proven reserves were established at 196,000 tons.

In New Hampshire, Standard Metals Corp. began a drilling program near Milan in October as a followup of exploration which had been continuing since 1973. Low-grade zinc, copper, and lead mineralization was intersected with widths up to 150 feet. Encouraged by these results, Standard took an option on 240 square miles for further exploration expected to last at least 3 years.

SMELTER AND REFINERY PRODUCTION

U.S. slab zinc production at 7 primary plants and 13 secondary plants was 495,937 tons in 1975, a decrease of 22% from that of 1974. The decrease in production was attributable to the reduced level of economic activity during the year. The closing of ASARCO's zinc smelter at Amarillo, Tex., reduced domestic capacity to 652,000 tons per year.

Producer stocks increased sharply from 39,720 tons to 75,652 tons during the year. Domestic producers purchased 3,442 tons of GSA stockpile zinc during the year, all of which was remelted.

The portion of domestic slab zinc production from domestic ores was 62%, from foreign ores 26%, and from scrap 12%. Zinc produced from foreign ores decreased 38% from that of 1974, while production from domestic ores decreased 11%, and from scrap 26%.

Primary slab zinc produced at electrolytic refineries increased 2% over that of 1974, and was 47% of the total slab zinc produced. Zinc produced at retort plants was down 37% and made up 41% of the total. Redistilled slab zinc from secondary materials produced at primary smelters fell 38% and contributed 7% of the total; redistilled slab zinc at secondary smelters increased 3% and comprised 5% of the total. Distribution of slab zinc production by grades was Prime Western, 43%; Special High Grade, 49%; Intermediate, 3%; High Grade, 4%; and Brass Special, 1%.

The ASARCO zinc smelter at Amarillo, Tex., closed permanently on May 31, 1975. The old horizontal retort plant was considered obsolete and the cost of bringing the plant into compliance with clean air standards was regarded as prohibitive. In its 53 years of operation, the plant produced 2,094,345 tons of zinc, an annual average of nearly 40,000 tons. The 450 employees idled by the shutdown were largely absorbed by ASARCO's new copper refinery at Amarillo.

ASARCO issued a letter of intent to award a contract for the design of a new electrolytic refinery at Stephensport, Ky. The $160 million, 180,000-ton-per-year capacity zinc plant was to be built on a site already owned by ASARCO, but the actual construction date was suspended indefinitely.

National Zinc Co. continued construction of its Bartlesville, Okla., electrolytic smelter. The new $40 million smelter, rated at an annual capacity of 56,000 tons of slab zinc, was scheduled to replace the old 50,000-ton-per-year horizontal retort smelter at the same location by mid-June 1976. By yearend, purification and filtration buildings and facilities to house the melting and casting shops were completed. National Zinc had no plans to produce Special High Grade zinc, preferring to serve its traditional customers with lower grades, even though the standard product of electrolytic smelters is Special High Grade. National Zinc stated that by expanding the roaster capacity, smelter capacity may be increased by 15,000 tons in the future.

AMAX Zinc Co., Inc. continued to modernize its Sauget, Ill., electrolytic zinc plant. Full capacity of 84,000 tons of zinc was expected to be reached by the end of 1976. The plant produced 58,100 tons of zinc, all Special High Grade, in 1975. AMAX installed turbulent contact absorption towers for cooling the zinc electrolyte and completed the rebuilding of the electrolytic cell room. During 1975, AMAX spent $21.2 million of an alloted $26 million slated for the acquisition and modernization of the facility.

Bunker Hill produced 93,000 tons of slab zinc, a 1,000-ton increase from that of 1974. In August, Bunker Hill started operation of a State-approved sulfur dioxide abatement program designed to eliminate 72% of the sulfur dioxide emissions in the smelter stack gas. The plan required some curtailment of operations during adverse atmospheric conditions to prevent sulfur dioxide concentrations from exceeding ambient air standards. To overcome these restrictions, the company designed two new stacks, a 700-foot stack for the zinc smelter and a 610-foot stack for the lead smelter. In December, EPA displaced the Idaho regulations with stricter standards. Consequently, Bunker Hill filed for a judicial review and slowed construction on its $10 million stack project pending further negotiations. The completion of a $1.3 million program to capture dust from sintering operations was unaffected.

The New Jersey Zinc Co. and Union Minière, S.A. of Belgium, worked out partnership details for development of a new $97 million, 90,000-ton annual capacity zinc smelter at Clarksville, Tenn., scheduled for completion in 1979. New Jersey Zinc originally planned a 160,000-ton facility with completion set for 1976. The plant would be the first completely new domestic zinc refinery since 1941.

New Jersey Zinc also announced plans to consolidate all its research units at a new $3 million facility at Bethlehem, Pa. Studies will be conducted on ore evaluation, hydrometallurgy, extractive metallurgy, and chemical process technology. The 42,000-square-foot complex, named the Harold U. Zerve Research Center, was scheduled for completion by mid-1977.

By yearend, St. Joe Minerals Corp. spent $16.3 million of a $22.5 million bond issue sponsored in 1972 by a local development authority to finance water and air pollution controls on its Monaca, Pa. smelter. Another $14 million expenditure was anticipated to meet sulfur oxide and particulate emission control over the next 4 years with $2 million extra required for water pollution abatement.

The company-owned, coal-burning powerplant, which provides electricity for St. Joe's electrothermic smelter, was being considered as a demonstration project for the Federal Bureau of Mines citrate process for removing sulfur from stack emissions. St. Joe owns the coal mines which supply the powerplant.

Secondary Zinc Smelters.—Zinc recovered from zinc-bearing scrap was 283,201 tons in 1975, a 16% reduction from that recovered in 1974. Zinc-base scrap accounted for 58% of the total compared with 50% in 1974, while zinc recovered from copper-base scrap fell from 48% in 1974 to 41% in 1975. Recovery from new scrap continued to decrease, while that from old scrap continued to gain, the latter accounting for 27% of the total zinc recovered from scrap versus 22% in 1974. Of the total zinc recovered from scrap, 34% was recovered as zinc metal, 55% as alloys, mostly brass and bronze, and 11% as compounds, mostly zinc oxide.

Slag-Fuming Plants.—Slag-fuming plants processed hot and cold lead blast furnace slags and residues to produce zinc oxide fume. The oxide was either sold and used as oxide or sent to smelters and refineries for processing into metallic zinc. Three plants operated in 1975 as in 1974: ASARCO at El Paso, Tex., and East Helena, Mont., and The Bunker Hill Co., at Kellogg, Idaho.

Byproduct Sulfuric Acid.—In 1975, there were seven plants that roasted zinc sulfide concentrates and produced sulfuric acid, with one plant operating solely to produce calcine for processing to zinc oxide or slab zinc. In 1975, production of byproduct sulfuric acid from zinc plants was 711,769 tons, down from 830,969 tons produced in 1974.

Zinc Dust.—Production of zinc dust decreased 19% from that of 1974 to 40,875 tons in 1975. Zinc dust from distilled scrap accounted for 35,479 tons.

CONSUMPTION AND USES

About 620 facilities were canvassed for zinc consumption in 1975, compared with 670 in 1974. Of the total, 562 reported consuming zinc in 1975.

In 1975, slab zinc consumption declined 28% from that of 1974, and was off 38% from its high of 1,503,938 tons in 1973, a result of the economic slowdown that began in 1974 and continued into 1975. Industries that are large zinc consumers, such as automotive and housing, declined 31% and 43%, respectively, from 1973 to 1975.

Domestic consumption of slab zinc was 925,330 tons in 1975. The zinc content of the ore used directly in galvanizing or compounds was 82,732 tons, down from 127,113 tons in 1974. The zinc content of secondary materials to make alloys, zinc dust, and compounds was 223,753 tons, down from 258,204 tons in 1974. Total consumption of zinc for all classes was 1,231,815 tons, a decrease of 26% from that of 1974.

Slab zinc for galvanizing accounted for 376,887 tons (41%); zinc-base alloys, 334,191 tons (36%); brass products, 115,326 tons (12%); zinc oxide, 39,020 tons (4%); rolled zinc, 27,308 tons (3%); and other, 32,598 tons (4%).

Slab zinc consumption distributed by grade was Special High Grade, 438,173 tons (47%); High Grade, 83,369 tons (9%); Intermediate, 14,242 tons (2%); Brass Special, 79,214 tons (9%); Prime Western, 309,564 tons (33%); and Remelt, 768 tons (less than 0.1%). Consumption of all grades of slab zinc decreased from that of 1974. The most significant decline was that in Special High Grade zinc, which showed a loss of 134,678 tons, or 24%.

Slab zinc consumed at rolling mills was 27,308 tons in 1975, a decrease of 31% from that of 1974. Production of rolled zinc products decreased 28% to 27,725 tons. Strip and foil accounted for 76%, while 10% was used for photoengraving plates. Exports of wrought zinc decreased 53% to 1,629 tons, and imports decreased from 640 tons in 1974 to 236 tons. Production of rolled zinc from scrap was 22,153 tons in 1975, yielding a total production of 49,878 tons of rolled zinc during the year, compared with 71,891 tons in 1974.

The leading zinc consuming States in 1975 were Ohio with 129,254 tons (14%); Illinois, 123,067 tons (13%); Pennsylvania, 114,842 tons (12%); Indiana, 96,928 tons (10%); New York, 85,431 tons

(9%); and Michigan, 75,035 tons (8%). Ohio ranked highest in galvanizing and Michigan was the leader in diecasting.

In 1975, the Zinc Institute, Inc. conducted a survey of 438 diecasters to determine the consumption of zinc in 9 major market categories based on 1974 data. The results showed that automotive components accounted for 51.2% of the total; builders' hardware, 19.1%; domestic appliances, 8.5%; industrial, agricultural, and commercial machinery, 7.7%; electrical components, 5.7%; sporting goods and toys, 2.8%; scientific and professional equipment, 1.6%; sound and television equipment, 1.2%; and miscellaneous, 2.2%.

ZINC PIGMENTS AND SALTS

Production.—Published data for zinc pigments and compounds include zinc oxide and zinc sulfate. To avoid disclosing individual company confidential data, information for leaded zinc oxide, lithopone, and zinc chloride cannot be published.

Production of zinc oxide in 1975, at 165,400 tons, decreased 35% from that of 1974. Shipments were 2% higher than production. Zinc sulfate production, at 21,207 tons, showed a decrease of 54%.

The source of domestic zinc oxide production was 56% from ore and concentrate (American process), 29% from slab zinc (French process), and 15% from secondary material. Zinc sulfate production came from secondary material and from ore or intermediate products. Lead-free zinc oxide was produced at 14 plants in the United States, and leaded zinc oxide was produced at 1 plant. At least seven plants produced zinc sulfate and four produced zinc chloride.

Production of zinc oxide published by St. Joe Minerals Corp. was 46,914 tons, or 52% of capacity, down from 67,217 tons in 1974. Two other producers using ores or concentrates as a major source material were ASARCO with plants at Columbus, Ohio, and Hillsboro, Ill., and The New Jersey Zinc Co. Other major zinc oxide producers such as the Eagle-Picher Industries, Inc., Hillsboro, Ill., plant and the Sherwin-Williams Co., Coffeyville, Kans., plant, used calcines, fume, and secondary materials as raw materials. ASARCO, New Jersey Zinc, and St. Joe were the three producers of French process zinc oxide.

Consumption and Uses.—The apparent consumption of zinc oxide decreased 27% in 1975 to about 180,000 tons. Analysis of domestic shipments by industry usage showed the largest consumers to be the rubber industry with 57% of the total; photocopying, 15%; chemicals, 10%; and paints, 6%. The use of zinc oxide decreased in all categories. Agricultural use showed the largest decline, 70%, followed by chemicals, 50%; and ceramics, 48%. The large decline in agriculture shipments was attributed to consumers working down the excessive stock built up in the preceding year. Zinc oxide was also used in floor coverings, fabrics, lubricants, plastics, and rayon manufacturing. Agriculture was the chief use for zinc sulfate with lesser amounts assigned to rayon, flotation reagents, and chemicals. Leaded zinc oxide was used in rubber. Zinc chloride usage, a small part of zinc compound consumption, declined. Most of the chloride was used in soldering fluxes and batteries.

Prices.—Zinc oxide and compound prices remained stable during the year. For the first 4 months of 1975, prices ranged from 40 cents per pound for American process zinc oxide to 41.5 cents for French process zinc oxide, and from 42 to 44 cents for electrophotographic grade. Zinc oxide prices in April steadied at the higher end of the range after the March increase. In May, prices advanced to 40 to 41.75 cents for American process, 41.5 to 42.5 cents for French process, and 39 to 44 cents for electrophotographic grade. In July, electrophotographic grade climbed to 43 to 44 cents. At the end of the year quotations were 40 to 41 cents for American process, lead-free pigment grade, 41.5 cents for French process, and 43 to 44 cents for electrophotographic grade. Leaded zinc oxide, 12%, was quoted at 35.5 cents per pound compared with 37.25 cents in January 1975. The price of zinc sulfate, granular monohydrate industrial, 36% zinc, bags in car load lots, was reported as $24 to $26.50 per 100 pounds in December, up from $24 per 100 pounds a year earlier.

Foreign Trade.—Exports of zinc oxide decreased 75% from that of 1974 to 3,104 tons, of which 2,389 tons was pigment grade. Canada and Mexico received about 60% of the total. Lithopone exports decreased by 23% to 917 tons. Imports of almost all classes of zinc compounds decreased in 1975 to a total of 18,447 tons, a 53% loss. As in 1974, zinc oxide, although it declined 49% to 13,817 tons, was the major component of imports of zinc compounds. Mexico and Canada supplied 99% of the total with European Community countries contributing most of the remainder.

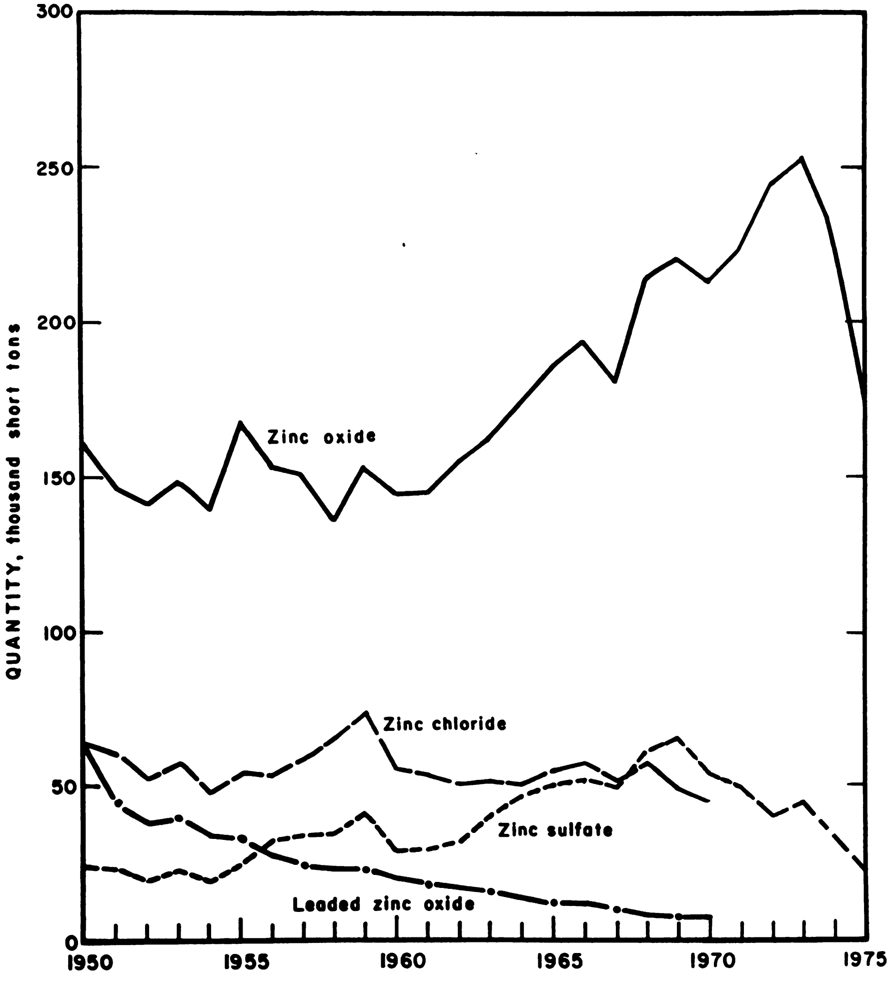

Figure 4.—Trends in shipment of zinc pigments.

STOCKS

Producer Stocks.—Stocks of slab zinc at producer plants at the beginning of the year were 39,720 tons, increasing to 75,652 tons by yearend. The Zinc Institute, Inc. reported that producer stocks climbed steadily to almost 116,000 tons in June, but then declined for the remainder of the year.

Consumer Stocks.—Slab zinc inventories at consumer plants were 211,158 tons at the beginning of the year, but by yearend consumer stocks had fallen to 107,276 tons. In the January to September period, consumer stocks fell to about 91,000 tons.

Government Stockpile.—During 1975 the GSA inventory was reduced from 391,600 tons to 385,714 tons.

PRICES

Effective January 1, 1975, National Zinc lowered its quote on Prime Western zinc by 0.5 cent per pound to 39 cents per pound. Slack demand, falling free market prices, and mounting producer inventories put downward pressure on prices.

ASARCO raised its list price for Prime Western from 35 to 38.5 cents per pound and revamped its premium-grade pricing system. The company, which had been selling zinc at the Metals Week average price, began giving its customers the option of buying at the Metals Week average or the list price. New Jersey Zinc lowered its price for Prime Western to 39 cents per pound, f.o.b. Palmerton, Pa., freight allowed.

By March the price quoted by U.S. producers ranged from 38 to 39 cents per pound for Prime Western and 39.5 cents per pound for Special High Grade. Most quotes were on a delivered basis. The industry pattern was to adjust prices on various grades to make them more competitive with foreign producers.

In September, New Jersey Zinc announced a price increase of 2 cents per pound effective October 10. On October 30, the company withdrew the increase when other U.S. producers did not follow suit. The average U.S. price for zinc in 1975 was 38.96 cents per pound.

In January, European zinc producers began withdrawing zinc warrants from London Metal Exchange (LME) warehouses to support the price by reducing the supply of uncommitted metal rather than buying and selling on the LME. This action pushed LME prices to £354 per metric ton (37.8 cents per pound U.S. equivalent) for Good Ordinary Brand (GOB) zinc (Prime Western equivalent). The producer price was £360 per metric ton (38.6 cents per pound). By May LME prices dipped to £319 (33.6 cents per pound). Production cuts by the European producers failed to stem falling prices. In June prices touched £309 (32.5 cents per pound), but producers became active and pushed the price to £330 (34.1 cents per pound). By midyear the weakness of the pound sterling put pressure on the continental producers to raise prices. At the end of August cash quotes reached £360 (34.5 cents per pound), the same as the producer price.

On October 8, two producers raised prices to £390 (36.1 cents per pound), citing the decline in sterling value as the chief reason. As other producers followed, LME prices advanced from £337 per metric ton (31.2 cents per pound) to £345 (32.1 cents per pound) in late November. In December, Electrolytic Zinc of Australasia Ltd. precipitated the move to a dollar quote of $795 per metric ton (36.1 cents per pound) because of problems with currency alinements. By yearend the dollar quote was accepted by all major European zinc producers, in addition to Canadian and Australian producers.

In February, U.S. dealer prices for Special High Grade zinc were 34.5 to 36 cents per pound. Dealers quoted 35 to 35.5 cents per pound for Special High Grade in May, but business was slow. In late August quotes for Special High Grade climbed to 37.25 to 38 cents per pound as demand improved. By December U.S. dealer Special High Grade was down to 35 cents per pound compared with 39.5 cents per pound for producer metal.

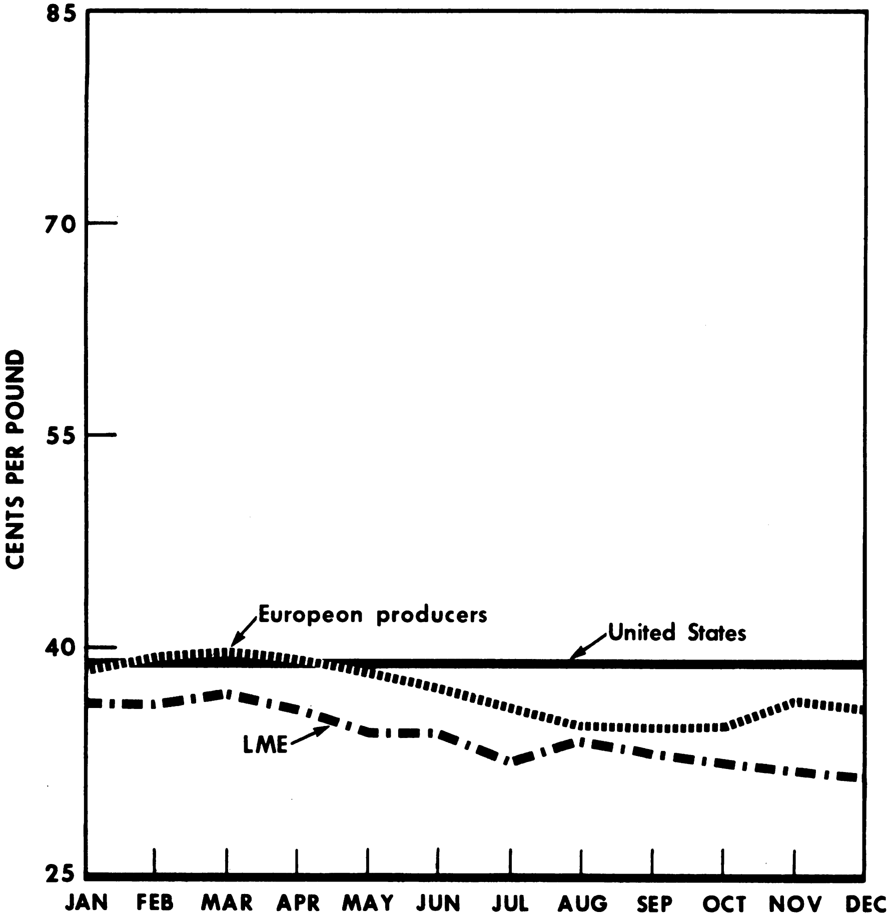

Figure 5.—Average monthly prices in 1975 for U.S. Prime Western zinc and equivalent foreign grade.

FOREIGN TRADE

Exports of unwrought zinc and alloys was 9,627 tons in 1975, a 75% decrease from that of 1974. The Netherlands received 43% of the exports; Brazil, 18%; and Venezuela, 14%. Wrought zinc and zinc alloy exports were 13,095 tons in 1975, of which 62% went to Belgium-Luxembourg and 24% to Canada.

General imports of zinc in ore were 144,987 tons in 1975, a decrease of 40% from that of 1974. Canada supplied 68% and Honduras increased its portion to 9%. General imports of zinc metal were 380,437 tons, a decrease of 29% from that of 1974. Canada supplied 48% of the total; Spain, 7%; and Australia, 6%. Other leading suppliers, in decreasing order, were Finland, Peru, Belgium-Luxembourg, West Germany, and Mexico. Since 1973, zinc metal from Angola, Italy, Liberia, the Netherlands, Spain, and the Republic of South Africa has entered the U.S. market in increasing amounts, whereas less zinc has been imported from Australia, Belgium-Luxembourg, Canada, France, Japan, Poland, the United Kingdom, and Zaire.

Imports of ore for consumption were 428,544 tons in 1975, an increase of 220% over that of 1974. With the removal of the tariff on ores and concentrates in early August, 329,934 tons of zinc in concentrates was withdrawn from bonded warehouses in the last 5 months of the year. Metal imports for consumption was 374,922 tons in 1975, 31% less than in 1974.

There were no changes in the basic tariff rates in 1975 for slab zinc at 0.7 cent per pound, and zinc dust at 0.3 cent per pound. The duty rate for unwrought alloys of zinc, which includes diecasting alloys, was 19% ad valorem. On August 9, the duty of 0.67 cent per pound on zinc ores, concentrates, zinc-bearing materials, and zinc scrap (including skimmings and drosses) was suspended until June 30, 1978, as provided by Public Law 94–89.

WORLD REVIEW

Preliminary data from the World Bureau of Metal Statistics[4] indicated that the world consumption of zinc fell 14% from that of 1974. Australia and Western Europe suffered declines in consumption of about 23%, but Africa and centrally planned economy (CPE) countries as a group showed almost no change. Bureau of Mines data showed world mine production down 2%, and slab zinc production down 8%, from 1974 levels. In mining, declines in tonnage mined were especially noted in Canada, Greenland, Iran, Mexico, Thailand, the United States, Zaire, and Zambia. Australia, the Republic of South Africa, and Japan increased production significantly, and the CPE countries gained slightly. Tonnage declines in smelter production were most prominent in Australia, Belgium, France, West Germany, Japan and the United States, but production in the Netherlands and the Republic of Korea increased as new smelters came onstream. Zinc metal production in CPE countries increased slightly from that of 1974.

Stocks in LME warehouses increased from 14,000 tons in January to almost 70,000 tons by yearend. Most of the increase occurred in the last 4 months of the year. Producer stocks worldwide doubled to about 820,000 tons during the year. European producers held about 270,000 tons, Japanese producers about 240,000 tons, and other countries the remainder.[5]

In 1975, the net trade in slab zinc between market economy countries, including Yugoslavia and CPE countries, was a surplus of about 77,000 tons.

Australia.—Zinc production from the Mount Isa mine in Queensland, operated by Mount Isa Mines Ltd., was 126,000 tons, up from 113,400 tons in 1974. Zinc metal reserves at the mine were 3.4 million tons. Development of the new Hilton lead-zinc-silver mine continued, where reserves were 41 million tons of ore grading 9.6% zinc and 7.7% lead. The company completed its 55-ton-per-day pilot plant at the McArthur River lead-zinc-silver deposit in the Northern Territory. The orebody contained proven reserves of 210 million tons of ore assaying 9.5% zinc.

Cobar Mines Pty. Ltd. produced 7,320 tons of zinc, based on an assay of 47.7% zinc for the concentrate, from the Cobar mine in New South Wales. At the West Coast mine in Tasmania, comprised of the Rosebery, Hercules, and Farrell mines, EZ Industries Ltd. produced 63,014 tons of zinc from ore grading 12.8% zinc. The company also treated zinc-rich tailings at the site. Reserves, expressed as zinc metal, were given as 1.1 million tons. Mining of the willemite (zinc silicate) ore deposit at Beltana, South Australia continued, with 10,206 tons being shipped to the Risdon smelter and 26,059 tons being exported. Exploration of the Elura prospect near Cobar indicated a resource of about 20 million tons of lead-zinc-silver ore grading about 8.4% zinc.

The mines of Australian Mining and Smelting Ltd. produced 226,000 tons of zinc contained in 434,000 tons of concentrate. Ore milled was 2,030,000 tons, a level higher than that of 1974 despite the shortage of experienced miners. The capacity of the flotation mill was increased and a new plant to treat mine dump residues was nearing completion.

EZ Industries Ltd. produced 167,673 tons of zinc metal and 7,321 tons of zinc dust from its Risdon smelter in the fiscal year ending June 30, 1975. Production cuts led to a capacity utilization of 60% by yearend. Production at the Cockle Creek smelter of Sulfide Corporation Pty. Ltd., which operated at about 65% of capacity most of the year, was 45,000 tons. Pollution control equipment was installed at a cost of $2.4 million. The Broken Hill Associated Smelters Pty. Ltd. embarked on a $9 million pollution control program at its Port Pirie smelter which produced 31,000 tons of zinc in 1975.

[5] International Lead and Zinc Study Group. Lead and Zinc Statistics, Monthly Bulletin. V. 16, No. 6, June 1976, p. 6.

Bolivia.—Corporación Minera de Bolivia (COMIBOL) produced about one-half of the total Bolivian zinc production from ore grading 10.3% zinc. COMIBOL reported measured and indicated recoverable reserves at yearend 1974 to be 1.5 million tons of ore grading 13.3% zinc and 1.3% lead. In addition, low-grade reserves contain another 19,000 tons of zinc and inferred reserves contain 94,000 tons of zinc.

ASARCO Incorporated, through a wholly-owned subsidiary, acquired a 58% interest in a new Bolivian corporation to operate the Quioma lead-zinc-silver mines. The new corporation will more than double annual capacity to 6,800 tons of zinc and 4,000 tons of lead in concentrates.

Dowa Mining Co. announced plans to explore for zinc in central Bolivia in a joint venture with COMIBOL. Australian Mining and Smelting Ltd. was also reported to be exploring for zinc.

Brazil.—Brazilian, Spanish, Belgian, and British interests formed a new company, Cia. Paraibuna de Metais, S.A., to build a 33,000-ton-per-year electrolytic refinery at Juiz de Fora. The expanded electrolytic smelter of Cia. Mineira de Metais, S.A., at 42,000 tons per year, was scheduled for completion in 1976.

Canada.—Mine output, at 1,193,809 tons, was 7% lower than that of 1974. Depleted reserves forced the closure of the Annex mine in British Columbia, and the Joutel and Normetal mines in Quebec. In August, the Daniel's Harbor mine, jointly owned by Tecam Ltd. (63.4%) and AMAX Zinc (Newfoundland) Ltd. (36.6%), was opened in Newfoundland. In Quebec, Société Minière Louvem started operations in January, and late in the year Lemoine Mines Ltd. brought its mine in the Chibougamau region into production.[6]

The leading producing provinces were Ontario with 31% of the total zinc production, followed by New Brunswick, 17%; Northwest Territories, 12%; and Quebec and the Yukon, 11% each. Data for the principal producing mines are given in table 2. Metal output was 470,600 tons, about 700 tons greater than that of 1974. Consumption of zinc was 110,000 tons, about 10% below that of 1974.

Texasgulf Inc. mined about 2.27 million tons of ore from the open pit and about 1.36 million tons from underground workings at the Kidd Creek mine in Timmins, Ontario. By the end of 1976, all mining will be underground as development progresses down to the 1,600-foot level. The program to increase mine capacity to 5 million tons of ore per year by the addition of the No. 2 underground mine and fourth concentrator circuit was on schedule. The drilling program to outline ore below the 2,800-foot level indicated ore to at least the 5,000-foot level. Mattabi Mines Ltd. exported about 95% of its production from the Mattabi mine north of Ignace. The Lyon Lake Division of Mattagami Lake Mines Ltd. completed installation of a mining facility, with production scheduled for late 1977. Ore reserves at the mine, located 5 miles from the Mattabi mine, were given at 4 million tons averaging 6.66% zinc with lesser quantities of copper, lead, silver, and gold.

In New Brunswick, Brunswick Mining & Smelting Corp. Ltd. continued its expansion of the No. 12 mine to increase capacity to 11,000 tons per day by 1979. The company experienced a total operating cost per ton of ore milled of $15.81,[7] compared with $12.89 in 1974 at its No. 12 underground mine, and $9.83 at the open pit mine, up from $8.41 in 1974. Texasgulf established more than 6 million tons of zinc-copper-lead mineralization at its Half Mile Lake project.

On Baffin Island in the Northwest Territories, Nanisivik Mines Ltd., in which Texasgulf has a 35% net profits interest, planned to begin production in late 1976 at the rate of about 130,000 tons of zinc concentrate per year. Another Texasgulf property, the Izok Lake sulfide deposit, contains 7 million tons of ore assaying 14.8% zinc which is suitable for open pit mining. Two other zones, the Hood River Nos. 10 and 41, contain an additional

[7] Where necessary values have been converted from Canadian dollars to U.S. dollars at the rate of CAN $1.017=US$1.00.

820,000 tons averaging 3.74% zinc. Pine Point Mines Ltd. found a new ore body of 600,000 tons grading 17% combined zinc-lead.

Mattagami Lake Mines, Ltd. shipped 85% of its zinc concentrate from the Mattagami mine in Quebec to the Valleyfield smelter in Quebec; 10% of the concentrate was exported, and 5% was stockpiled. Orchan Mines Ltd. ceased operations at Garon Lake at yearend because of depletion of the ore.

The new zinc mine near Daniel's Harbor, Newfoundland, operated by the Newfoundland Zinc Division of Tecam Ltd., was put into operation in July at a cost of almost $18 million. Several small ore bodies mined by open pit methods supplied the mill material until completion of the underground development. Tecam's 63.4% share of the concentrate is refined in Canada. Operating cost per ton of ore milled was $8.94.

In Manitoba, ore production by Hudson Bay Mining & Smelting Co., Ltd. was 100,657 tons less than that of 1974 because of labor shortages and development work in the Flin Flon-Snow Lake area. Development work continued on the Centennial and Westarm mines. Production costs at the underground Fox mine of Sherritt Gordon Mines Ltd. increased from $12.49 in 1974, to $14.69 per ton of ore milled, and from $8.58 in 1974, to $10.80 at the open pit Ruttan mine.

Texasgulf Canada Ltd. produced 93,000 tons of zinc metal at its smelter in Ontario, down from 107,900 tons in 1974. Cominco Ltd. produced 194,000 tons at Trail, B.C., up from 162,000 tons in 1974. A new 850-ton-per-day sulfuric acid plant began operation, replacing two older ones. Canadian Electrolytic Zinc Ltd. had almost completed a 50% expansion of its Valleyfield, Quebec smelter by yearend. The capacity increase to 225,000 tons per year will cost about $61 million. Production of metal in 1975 was 117,700 tons, compared with 134,800 tons in 1974. Hudson Bay Mining & Smelting Co., Ltd. produced 65,118 tons of zinc.

Canadian zinc reserves on January 1, 1975, were given as 31.2 million tons at the producing mines and deposits under development, and an additional 7.3 million tons in undeveloped deposits for which production is foreseen.[8] The Provinces of New Brunswick and Ontario contain about one-half of the reserves at producing properties, whereas the Yukon and Northwest Territories hold most of the reserves slated for future production.

[1] Ore produced.

[2] Combined and zinc content.

[3] Recoverable.

[4] Six months operation to December 31, 1975.

[5] Mine closed June 30, 1975.

[6] Mine closed April 29, 1975.

[7] After dilution.

[8] Milled mine output from Cupra, D'Estrie, and Clinton mines in fiscal year ending August 31, 1975.

[9] Ore milled on toll by Manitou-Barvue Mines Ltd.

[10] Development ore from operations beginning in November.

Source: Company Annual Reports and Department of Energy, Mines and Resources, Ottawa, Canada.

Denmark.—The Black Angel mine in Greenland, owned by Greenex A/S, produced 168,000 tons of zinc concentrate from 651,000 tons of mined ore. A mile-long tunnel connecting the Angel and Cover zones was completed, which resulted in the delineation of over 1.2 million tons of ore assaying 14.1% zinc, 4% lead, and 1 ounce of silver per ton.

France.—Cie. Royale Asturienne des Mines produced 57,000 tons of zinc metal at its Auby plant, compared with 91,000 tons in 1974, because of the changeover from vertical retorts to the new 110,000-ton-per-year electrolytic refinery. Most of the feed material was supplied by Canada and Sweden. The company entered the U.S. market in 1975 through the creation of a sales corporation, Asturmet, Inc.

Honduras.–Production from the El Mochito mine of Rosario Resources Corp. was 346,352 tons grading 8.69% zinc, 7.82% lead, 10.98 ounces of silver per ton, and minor quantities of gold. Zinc in concentrate was 24,321 tons. Reserves increased by over 527,000 tons to 6.3 million tons averaging 8.07% zinc and 4.78% lead.

India.—A new 33,000-ton-per-year electrolytic smelter was under construction by Hindustan Zinc, Ltd. at Visakhapatnam. The capacity of the smelter at Debari was being increased to 50,000 tons per year from its current capacity of 20,000 tons. Both smelters should be operational in 1976. Production of zinc metal by Cominco Binani Zinc Ltd. was reduced to 9,900 tons in 1974 because of delayed shipments of concentrate.

Ireland.—The principal uncertainties in connection with the Navan lead-zinc mine were resolved in September when the Irish Government and Tara Mines Ltd. formally executed a mining lease, thereby allowing resumption of construction activity. The equity of Tara Mines would be owned 75% by Tara Exploration and Development Co. Ltd., and 25% by the Irish Ministry for Industry and Commerce, which would also collect royalty payments of 4.5% of pretax income. The mine was expected to provide about 2.5 million tons of ore per year to the 7,500-ton-per-day concentrator during the 25-year lease. About 500,000 tons of lead and zinc concentrates will be transported by rail to the shipping facility at Dublin. Tara expected recoveries for zinc and lead of 90% and 82%, respectively, from ore assaying 11% zinc and 2.4% lead. About 800 people will be employed in the mining operation.

During the year, Northgate Exploration Ltd. treated 648,477 tons of ore from the Tynagh mine, County Galway. The ore grade was 4.27% zinc compared with 4.38% in 1974. Metallurgical recovery of zinc was 80.4%, up from 77.8% in 1974. Payable metal in concentrate was 17,350 tons. Direct operating costs per ton of ore mined during 1975 were $13.55, up from $10.51 in 1974. Ore reserves were given at 2.4 million tons assaying 3.55% lead, 3.61% zinc, 0.21% copper, and 1.16 ounces of silver per ton. At the Tatestown zinc-lead prospect in the Navan area, Northgate indicated the possibility of a deposit containing 6.7% combined zinc and lead.

Bula Ltd., 49% owned by the Irish Government, reported ore reserves at Navan of 21.6 million tons grading 8% combined lead and zinc. Bula stated that a mining plan for the Navan deposit will necessitate diversion of the Blackwater River or a substantial safety pillar as a barrier between the river and the workings.

Mogul of Ireland Ltd. mined 987,984 tons of ore, about 15% of which came from pillar recovery areas. The milled tonnage was 1,012,686 tons grading 6.01% zinc and 2.67% lead. Operating costs increased 16% over those of 1974, with energy costs increasing 50%. Ore reserves after dilution were 5.9 million tons grading 6.36% zinc and 2.53% lead

Japan.—Japanese zinc metal producers operated at about 70% of capacity in 1975, turning out 773,600 tons of metal compared with 936,850 tons in 1974. Zinc exports declined 54% from that of 1974, mainly because of sharply lower shipments to the United States. Imports of zinc concentrates declined by 25% in 1975 as Japanese producers prevailed upon Australian and Peruvian suppliers to curtail shipments. At yearend negotiations were underway with Cyprus Anvil Mining Corp. of Canada to reduce concentrate shipments by 30%.

In October, Hachinohoe Smelting Co. increased its smelting charge by $27 per ton to about $180 per ton for zinc metal, and Akita Zinc Co. Ltd. increased its charge to about $205 per ton to be in effect until March 1976, in an effort to offset higher costs of energy and pollution abatement. Mitsui Mining & Smelting Co.

Ltd. closed its smelter in Kamioka for a month but increased production proportionately at its two other smelters in an economy move.

Mexico.—Industrial Minera Mexico, S.A. completed expansion of its Taxco silver-lead-zinc mine, including doubling the capacity at the old concentrator. The company negotiated a $150 million loan, most of which will be used to construct a 125,000-ton-per-year electrolytic refinery at San Luis Potosí. Detailed engineering of the plant was underway. Other projects included expansion of existing mines and the reopening of old mines. The lead-zinc mine at Parral was closed due to depletion of reserves, although the mill continued custom operation for other local mines.

Cía. Fresnillo, S.A. brought its 8,000-ton-per-year zinc-lead mine at Zimapan onstream in 1975. The company stated its reserves as 5.8 million tons grading 3.9% zinc, 3.6% lead, 0.39% copper, and 4.26 ounces of silver per ton of ore. Texasgulf Inc. extended its reserves at the Rio Murga property to 9 million tons grading about 1% zinc. Explomin, S.A., a company formed by Comisión de Fomento Minero (33%), Placer Development Co. (34%), and a Mexican group, Bancomer (33%), was considering the development of the Real de Angeles property in Zacatecas. Reserves of 45 million tons of ore grading 1% zinc and 0.9% lead were identified.

The production of refined zinc by Industria Peñoles, S.A. at its Torreon electrolytic plant increased to 75,498 tons, 32% over that of 1974.

Nicaragua.—Neptune Mining Co., 51.8% owned by ASARCO, treated 181,138 tons of ore averaging 7.2% zinc and 1% lead. Reserves in the Vesubio, Pioneer, and Venus mines were estimated at 1.2 million tons grading 9.78% zinc and 1.23% lead, with lesser amounts of copper, silver, and gold.

Peru.—Belgium and West Germany granted loans to Minero Perú to help finance the new Cajamarquilla zinc smelter scheduled for startup in 1978. Centromin, the former Cerro de Pasco operation, was planning to increase capacity of its La Oroya smelter to 143,000 tons of zinc per year by 1980. The first part of the expansion program currently under way will increase capacity to 100,000 tons per year in 1976.

Cía. Minerales Santander, Inc. a subsidiary of St. Joe Minerals Corp., produced 49,103 tons of zinc concentrate for export, down from 67,478 tons in 1974, because of unsettled labor conditions. Cía. de Minas Buenaventura S.A. began production from a new 200-ton-per-day mill at Colquicocha, Cajatambo Province, that should produce about 1,500 tons of zinc metal per year. Cía. Minera San Ignacia de Morococha S.A. began expansion of its plant facilities at the San Vicente mine to 50,000 tons of zinc per year from the current level of about 33,000 tons.

Cía. Minera del Madrigal, a division of Homestake Mining Co., milled 259,724 tons of copper-lead-zinc ore grading 5% zinc to produce 17,885 tons of zinc concentrate. The capacity of the plant was being increased from 770 tons to about 1,100 tons per day. ASARCO, through Northern Peru Mining Corp., produced 4,400 tons of zinc from the Quiruvilca mine.

South Africa, Republic of.—Phelps Dodge Corp. pinpointed three orebodies at Aggenys in northern Cape Province and has begun developing the Broken Hill deposit. Total reserves at two locations were given as 2.3 million tons of zinc, 5.7 million tons of lead, 900,000 tons of copper, and 200 million ounces of silver. Much of the ore is amenable to open pit mining. The metal content of the third area was estimated to be 1.9 million tons of zinc, 800,000 tons of lead, and 33 million ounces of silver.

Newmont Mining Corp. and O'Okiep Copper Co. continued metallurgical testing and underground work on the Gamsburg zinc deposit in Cape Province. Ore reserves were estimated at 94 million tons averaging 7.4% zinc and 0.55% lead before dilution. A 50-ton-per-day pilot plant was built to treat the ore. It was reported that the presence of about 3% manganese in the concentrates constitutes a potential problem in electrolytic refining.

South West Africa.—At the Tsumeb mine, Tsumeb Corp. Ltd. mined and milled 466,827 tons of ore grading 2.47% zinc, 9.73% lead, and 4.27% copper, slightly lower than production in 1974. The zinc mill recovery rate was 16.6%, yielding 3,729 tons of zinc concentrate averaging 51.3% zinc and 0.94% cadmium. Ore reserves at the mine at yearend were estimated at 5.6 million tons containing 7.75% lead, 4.56% copper, and 2.06% zinc.

Spain.—Cominco Europe N/V reported

that the Rubiales mine was expected to start up in the last quarter of 1976. Ore reserves were 11 million tons containing 1.3 million tons of combined lead and zinc.

Development of the d'Aznacollar mine at Seville by d'Aznacollar d'Andaluza de Piritas, S.A. proceeded toward a 1978 opening. Reserves at the open pit mine were evaluated at 48 million tons grading 3.33% zinc, 1.74% lead, and lesser quantities of copper and silver. The expected production rate is 53,000 tons of zinc per year.

Capacity at the San Juan de Nieva electrolytic smelter was increased to 130,000 tons per year.

Thailand.—Thai Zinc Co. Ltd., began construction of its 66,000-ton-per-year smelter to process the silicate-carbonate zinc ore being mined at Mae Sot. About half of the smelter output will supply Thailand's annual demand; the remainder will be exported. Since three Japanese zinc producers who were prospective partners in the project declined to participate, The New Jersey Zinc Co., owner of Thai Zinc, was looking for an equity participant in the venture. The Thai Government will receive the standard royalty of 2.5% of the value of the metal, as well as a special royalty of $5.44 per ton. Total reserves at the mine were estimated at 3.9 million tons grading 25% zinc.

United Kingdom.—Production of slab zinc was 70,636 tons, 24% below that of 1974. In November, the smelter at Avonmouth was closed for maintenance, but a labor dispute arose which kept the smelter closed for the remainder of the year.

Yugoslavia.—Ore reserves at the Veliki Majdan zinc-lead mine in Serbia were considerably increased. Mine production could double in the next several years to 120,000 tons of ore per year.

TECHNOLOGY

At the Bureau of Mines Salt Lake City (Utah) Metallurgy Research Center work continued on the recovery of zinc from the nonferrous fraction of automobile scrap. Investigations of techniques for recovering zinc from zinc-base wastes as an alternate to pyrometallurgical methods were pursued at the College Park (Md.) Metallurgy Research Center. At the Rolla (Mo.) Metallurgy Research Center work progressed on methods of recovering zinc with minimal pollution, development of improved lead dioxide anodes and pure zinc cathodes for the electrolytic process, and the utilization of zinc concentrates containing excessive quantities of deleterious metals, including copper and nickel. A pilot plant for the aqueous chlorine leaching of 500 pounds per day of lead-zinc concentrates and recovery of metal values was being constructed at the Reno (Nev.) Metallurgy Research Center. Another project involved the electrowinning of zinc from fused salts.

Results of several research investigations were published by the Bureau of Mines.[9]

A review of recent improvements in leaching techniques in the electrolytic zinc process was published,[10] as were reports on combined zinc-lead smelting and energy consumption.[11] For the industry, the weighted average of energy consumption per ton of zinc produced was 65 x 10^6 Btu.

A comprehensive coverage of zinc-related investigations and an extensive review of current world literature on the uses of zinc and its products are contained in bimonthly issues of the 1975 Zinc Abstracts published by the Zinc Institute, Inc., New York, and provided free of charge.

Progress reports of the projects supported by the International Lead Zinc Research Organization, Inc. are released annually in the ILZRO Research Digest.

W Withheld to avoid disclosing individual company confidential data.

[1] Zinc ore and ore from "other sources" combined to avoid disclosing individual company confidential data.

[2] Other States includes Illinois, Oregon, Washington, and Wisconsin.

[3] Lead and zinc recovered from copper, gold, silver, and fluorspar ores, and from mill tailings and miscellaneous cleanups.

Table 6.—Twenty-five leading zinc-producing mines in the United States in 1975 in order of output

Rank	Mine	County and State	Operator	Source of zinc
1	Balmat	St. Lawrence, N.Y	St. Joe Minerals Corp	Zinc ore.
2	Buick	Iron, Mo	AMAX Lead Co. of Missouri	Lead ore.
3	Sterling	Sussex, N.J	New Jersey Zinc Co	Zinc ore.
4	Bunker Hill	Shoshone, Idaho	The Bunker Hill Co	Lead-zinc ore.
5	Friedensville	Lehigh, Pa	New Jersey Zinc Co	Zinc ore.
6	Zinc Mine Works	Jefferson, Tenn	United States Steel Corp	Do.
7	Young	do	ASARCO Incorporated	Do.
8	New Market	do	do	Do.
9	Austinville and Ivanhoe	Wythe, Va	New Jersey Zinc Co	Do.
10	Star Unit	Shoshone, Idaho	The Bunker Hill Co. and Hecla Mining Co.	Lead-zinc ore.
11	Eagle	Eagle, Colo	New Jersey Zinc Co	Zinc ore.
12	Burgin	Utah, Utah	Kennecott Copper Corp	Lead-zinc ore.
13	Immel	Knox, Tenn	ASARCO Incorporated	Zinc ore.
14	Leadville	Lake, Colo	do	Lead-zinc ore.
15	Ground Hog	Grant, N. Mex	do	Do.
16	Pend Oreille	Pend Oreille, Wash	The Bunker Hill Co	Do.
17	Idarado	Ouray, and San Miguel, Colo.	Idarado Mining Co	Copper-lead-zinc ore.
18	Magmont	Iron, Mo	Cominco American Inc	Lead ore.
19	Bruce	Yavapai, Ariz	Cyprus Mines Corp	Copper-zinc ore.
20	Blue Hill	Hancock, Maine	Kerramerican Inc	Zinc ore.
21	Edwards	St. Lawrence, N.Y	St. Joe Minerals Corp	Do.
22	Elmwood	Smith, Tenn	New Jersey Zinc Co	Do.
23	Jefferson City	Jefferson, Tenn	do	Do.
24	Ontario	Summit, Utah	Park City Ventures	Lead-zinc ore.
25	Brushy Creek	Reynolds, Mo	St. Joe Minerals Corp	Lead ore.

Table 7.—Primary and redistilled secondary slab zinc produced in the United States[1]

(Short tons)

	1971	1972	1973	1974	1975
Primary:					
From domestic ores	403,750	400,969	399,119	346,993	307,959
From foreign ores	362,683	232,211	184,360	208,195	130,092
Total	766,433	633,180	583,479	555,188	438,051
Redistilled secondary	80,923	73,718	83,187	78,535	57,886
Total (excludes zinc recovered by remelting)	847,356	706,898	666,666	633,723	495,937

[1] Excludes processed GSA zinc.

Table 8.—Distilled and electrolytic zinc, primary and secondary, produced in the United States, by method of reduction

(Short tons)

Method of reduction	1971	1972	1973	1974	1975
Electrolytic primary	321,517	259,816	211,921	227,430	232,059
Distilled	444,916	373,364	371,558	327,758	205,992
Redistilled secondary:					
At primary smelters	68,612	63,034	67,758	56,342	34,931
At secondary smelters	12,311	10,684	15,429	22,193	22,955
Total	847,356	706,898	666,666	633,723	495,937

Table 9.—Distilled and electrolytic zinc, primary and secondary, produced in the United States, by grade

(Short tons)

Grade	1971	1972	1973	1974	1975
Special High	367,609	310,074	275,665	277,024	242,128
High	73,314	44,782	25,900	16,912	18,913
Intermediate	58,240	43,353	38,239	22,818	13,104
Brass Special	71,100	76,954	60,034	9,694	5,629
Prime Western	277,093	231,735	266,828	307,275	216,163
Total	847,356	706,898	666,666	633,723	495,937

Table 10.—Primary slab zinc produced in the United States, by State where smelted

(Short tons)

State	1971	1972	1973	1974	1975
Idaho	94,012	101,743	98,321	92,321	92,300
Illinois	46,389	--	26,616	55,527	55,337
Montana	115,480	69,754	--	--	--
Oklahoma	126,908	114,162	77,819	43,187	35,071
Pennsylvania [1]	228,651	210,860	250,752	240,891	152,280
Texas	154,993	186,661	129,971	123,262	103,063
Total	766,433	683,180	583,479	555,188	438,051

[1] Prior to 1972, included West Virginia.

Table 11.—Annual slab zinc capacity of primary zinc plants in the United States in 1975

Type of plant	Plant location	Slab zinc capacity (short tons)
Electrolytic plants:		
Amax Zinc Co., Inc	Sauget, Ill	84,000
ASARCO, Incorporated	Corpus Christi, Tex	100,000
The Bunker Hill Co	Kellogg, Idaho	104,000
Horizontal-retort plants:		
ASARCO, Incorporated [1]	Amarillo, Tex	53,000
National Zinc Co	Bartlesville, Okla	56,000
Vertical-retort plants:		
New Jersey Zinc Co	Palmerton, Pa	118,000
St. Joe Minerals Corp	Monaca, Pa	190,000

[1] Plant closed May 1975.

Table 12.—Secondary slab zinc plants, by group capacity, in the United States in 1975

Company	Plant location	Slab zinc capacity (short tons)
Alger Pattern Works Inc	Indianapolis, Ind	48,500
Arco Die Cast & Metals Inc	Detroit, Mich	
Belmont Smelting & Refining Works	Brooklyn, N.Y	
W. J. Bullock, Inc	Fairfield, Ala	
Gulf Reduction Co	Houston, Tex	
Hugo Neu-Proler Co	Terminal Island, Calif	
Illinois Smelting & Refining Co	Chicago, Ill	
New England Smelting Works Inc	West Springfield, Mass	
Pacific Smelting Co	Torrance, Calif	
Peerless Alloy Inc	Denver, Colo	
Proler International Corp	Houston, Tex	
Prolerized Schiabo Neu Co	Jersey City, N.J	
S–G Metals Industries, Inc	Kansas City, Kans	

Table 13.—Stocks and consumption of new and old zinc scrap in the United States in 1975

(Short tons, zinc content)

Class of consumer and type of scrap	Stocks Jan. 1	Receipts	Consumption			Stocks Dec. 31
			New scrap	Old scrap	Total	
Smelters and distillers:						
New clippings	252	1,001	1,199	--	1,199	54
Old zinc	288	5,795	--	5,460	5,460	623
Remelt zinc	7	1,317	1,324	--	1,324	--
Engravers' plates	174	1,172	--	1,116	1,116	230
Rod and die scrap	1,149	3,627	--	3,726	3,726	1,050
Diecastings	1,365	24,673	--	25,070	25,070	968
Fragmentized diecastings	2,599	13,678	--	14,866	14,866	1,411
Remelt die-cast slab	507	7,713	--	7,216	7,216	1,004
Skimmings and ashes	8,696	37,959	35,551	--	35,551	11,104
Sal skimmings	56	131	--	--	--	187
Die-cast skimmings	2,279	2,282	2,961	--	2,961	1,600

Table 14.—Production of zinc products from zinc-base scrap in the United States

(Short tons)

Products	1971	1972	1973	1974	1975
Redistilled slab zinc	80,923	73,718	83,187	78,535	57,886
Zinc dust	29,095	40,569	36,531	29,339	35,479
Remelt zinc	1,590	5,850	1,096	893	127
Remelt die-cast slab	18,339	13,555	12,595	12,358	4,829
Zinc-die and diecasting alloys	3,316	3,927	4,786	4,393	4,740
Galvanizing stocks	633	872	670	872	1,435
Secondary zinc in chemical products	45,312	50,047	56,591	56,275	31,972

Table 15.—Zinc recovered from scrap processed in the United States, by kind of scrap and form of recovery

(Short tons)

Kind of scrap	1974	1975	Form of recovery	1974	1975
New scrap:			As metal:		
Zinc-base	122,232	108,813	By distillation:		
Copper-base	136,791	97,476	Slab zinc[1]	78,535	57,886
Aluminum-base	3,750	--	Zinc dust	29,075	35,479
Magnesium-base	300	173	By remelting	1,743	1,562
Total	263,073	206,462	Total	109,353	94,927
Old scrap:			In zinc-base alloys	15,779	9,569
Zinc-base	45,722	56,605	In brass and bronze	148,751	145,009
Copper-base	25,733	19,686	In aluminum-base alloys	7,879	337
Aluminum-base	3,854	240	In magnesium-base alloys	445	393
Magnesium-base	100	208	In chemical products:		
			Zinc oxide (lead free)	32,104	19,329
Total	75,409	76,739	Zinc sulfate	9,838	4,373
			Zinc chloride	11,035	8,898
Grand total	338,482	283,201	Miscellaneous	3,298	366
			Total	229,129	188,274
			Grand total	338,482	283,201

[1] Includes zinc content of redistilled slab made from remelt die-cast slab.

Table 16.—Zinc dust produced in the United States

Year	Quantity (short tons)	Value	
		Total (thousands)	Average per pound
1971	50,259	$19,691	$0.196
1972	59,358	24,669	.208
1973	56,154	29,279	.261
1974	50,775	46,398	.457
1975	40,875	39,077	.478

Table 17.—Consumption of zinc in the United States

(Short tons)

	1971	1972	1973	1974	1975
Slab zinc	1,254,059	1,418,349	1,503,938	1,287,696	925,330
Ores (zinc content)[1]	119,254	118,305	129,651	127,113	82,732
Secondary (zinc content)[2]	277,381	307,369	298,336	258,204	223,753
Total	1,650,694	1,844,023	1,931,925	1,673,013	1,231,815

[1] Includes ore used directly in galvanizing.
[2] Excludes redistilled slab and remelt zinc.

Table 18.—Slab zinc consumption in the United States, by industry use

(Short tons)

Industry and product	1971	1972	1973	1974	1975
Galvanizing:					
Sheet and strip	255,335	294,205	321,927	291,008	185,795
Wire and wire rope	29,895	30,769	34,315	27,579	24,945
Tubes and pipe	65,122	64,549	68,048	59,995	47,180
Fittings (for tube and pipe)	10,240	11,106	11,969	9,294	6,359
Tanks and containers	2,759	3,645	2,941	3,203	1,917
Structural shapes	18,589	20,302	21,714	36,784	41,235
Fasteners	5,159	4,310	4,782	5,703	4,426
Pole-line hardware	8,358	8,437	8,193	6,783	4,934
Fencing, wire, cloth, and netting	20,232	21,995	25,418	26,284	20,051
Other and unspecified uses	59,063	58,886	64,530	56,636	40,045
Total	474,752	518,204	563,837	523,269	376,887
Brass products:					
Sheet, strip, and plate	78,929	105,405	109,582	99,971	64,958
Rod and wire	46,514	63,143	63,164	57,725	33,415
Tube	9,399	8,886	10,858	9,930	6,451
Castings and billets	4,479	6,840	6,000	4,431	3,079
Copper-base ingots	10,440	7,137	6,895	8,244	6,623
Other copper-base products	725	736	1,151	1,262	800
Total	150,486	192,147	197,650	181,563	115,326
Zinc-base alloy:					
Diecasting alloy	504,823	566,932	598,725	436,377	330,190
Dies and rod alloy	270	56	111	384	149
Slush and sand casting alloy	11,018	12,773	11,770	3,498	3,852
Total	516,111	579,761	610,606	440,259	334,191
Rolled zinc	38,852	45,216	40,763	39,393	27,308
Zinc oxide	40,043	51,992	61,734	65,376	39,020
Other uses:					
Light-metal alloys	4,575	6,300	7,466	9,690	5,832
Other [1]	29,240	24,729	21,882	28,146	26,766
Total	33,815	31,029	29,348	37,836	32,598
Grand total	1,254,059	1,418,349	1,503,938	1,287,696	925,330

[1] Includes zinc used in making zinc dust, wet batteries, desilverizing lead powder, alloys, chemicals, castings, and miscellaneous uses not elsewhere mentioned.

Table 19.—Slab zinc consumption in the United States in 1975, by grade and industry use

(Short tons)

Industry	Special High Grade	High Grade	Intermediate	Brass Special	Prime [1] Western	Remelt	Total
Galvanizing	21,306	18,126	6,735	75,056	255,195	469	376,887
Brass and bronze	33,937	58,797	26	3,987	18,473	106	115,326
Zinc-base alloys	332,905	608	9	55	421	193	334,191
Rolled zinc	19,377	361	7,472	--	98	--	27,308
Zinc oxide	16,717	1,126	--	--	21,177	--	39,020
Other	13,931	4,351	--	116	14,200	--	32,598
Total	438,173	83,369	14,242	79,214	309,564	768	925,330

[1] Includes select grade.

Table 20.—Rolled zinc produced and quantity available for consumption in the United States

	1974			1975		
		Value			Value	
	Short tons	Total (thousands)	Average per pound	Short tons	Total (thousands)	Average per pound
Production: [1]						
Photoengraving plate	6,367	$8,859	$0.696	2,898	$3,467	$0.598
Strip and foil	30,111	27,669	.459	21,010	22,699	.540
Total rolled zinc [2]	38,417	38,640	.503	27,725	31,155	.562
Exports	3,487	3,842	.551	1,629	2,086	.640
Imports	640	568	.445	236	507	1.074
Available for consumption	36,536	--	--	25,603	--	--

[1] Figures represent net production. In addition, 33,474 tons in 1974 and 22,153 tons in 1975 were rerolled from scrap originating in fabricating plants operating in connection with zinc-rolling mills.

[2] Includes other plate over 0.375 inch thick, sheet zinc less than 0.375 inch thick, and rod and wire. Bureau of Mines not at liberty to publish separately.

Undistributed	52,916	57,599	93,184	89,725	56,407
Total [4]	376,418	115,220	333,998	98,926	924,562

W Withheld to avoid disclosing individual company confidential data; included with "Undistributed."

[1] Includes brass mills, brass ingot makers, and brass foundries.

[2] Includes producers of zinc-base alloy for diecastings, stamping dies, and rods.

[3] Includes slab zinc used in rolled zinc products and in zinc oxide.

[4] Excludes remelt zinc.

Table 22.—Production and shipments of zinc pigments and compounds[1] in the United States

Pigment or compound	1974				1975			
	Production (short tons)	Shipments			Production (short tons)	Shipments		
		Quantity (short tons)	Value[2]			Quantity (short tons)	Value[2]	
			Total (thousands)	Average per ton			Total (thousands)	Average per ton
Zinc oxide[3]	256,355	232,542	$144,078	$620	165,400	169,485	$122,158	$721
Zinc sulfate	46,135	44,135	9,048	205	23,394	23,492	5,800	247

[1] Excludes leaded zinc oxide, lithopone, and zinc chloride; figures withheld to avoid disclosing individual company confidential data.
[2] Value at plant, exclusive of container.
[3] Zinc oxide containing 5% or more lead is classed as leaded zinc oxide.

Table 23.—Zinc content of zinc pigments[1] and compounds produced by domestic manufacturers, by source

(Short tons)

Pigment or compound	1974				1975

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, North Vietnam also produces zinc, but information is inadequate to make reliable estimates of output levels.

[2] Zinc content of concentrates.

[3] Recoverable metal.

[4] Sum of production of COMIBOL and exports by medium and small mines.

[5] Revised to zero.

[6] Data are compiled from company reports of Tsumeb Corp. Ltd., South-West Africa Co. Ltd. (ISCOR) for Imcor Zinc (Pty.) Ltd.'s Rosh Pinah mine. Data from Tsumeb Corp. Ltd. are for calendar years; data from other companies are for fiscal years ending June 30 of the year stated.

[7] Year beginning March 21 of that stated.

[8] Contained in zinc concentrates. Additional quantities of zinc may be contained as a byproduct in lead concentrates produced, but information is inadequate to make reliable estimates of such production, if any.

Zirconium and Hafnium

By Sarkis G. Ampian [1]

Zircon production and sales by domestic mining companies decreased nearly 30% in tonnage in 1975, and nearly doubled in value above that of 1974. Zircon exports decreased 13% from 21,487 tons in 1974 to 18,766 tons in 1975, while imports decreased 36% from 62,504 short tons in 1974 to 40,205 short tons in 1975. Exports of zirconium metal and alloys and zirconium oxide generally increased in 1975. Production of zirconium-bearing compounds for chemicals and refractories also increased slightly. Zircon consumption by foundries decreased from 80,000 short tons in 1974 to 46,200 tons in 1975. Some hafnium was also produced.

The 1975 worldwide zircon supply-demand picture was characterized by a softening in demand owing to the downturn in industrial activity coupled with an increase in Australian production capacity; the result was an oversupply, which depressed prices. Domestically, zircon reflected the worldwide situation except for the continued strong demand largely in manufacturing specialized refractories and abrasives.

Recycling of spent foundry zircon and substitution with chromite and aluminum silicate minerals for some zircon foundry applications were also commonplace.

Zircon use was primarily in foundry sands, refractories, abrasives, ceramics, and as a source of zirconium metal. The metal was used mostly in nuclear reactors and in corrosion-resistant equipment for industrial plants, and in refractory alloys. Hafnium was used in nuclear reactors, flashbulbs, and refractory alloys.

Legislation and Government Programs.—The Statistical Supplement to the Stockpile Report to Congress, December 31, 1974, showed no objectives for zirconium and hafnium materials. The U.S. Energy Research and Development Administration at its Pittsburgh Naval Reactors Office had on inventory as of June 30, 1975, approximately one-half ton of zirconium crystal bar and scrap, 937 tons of zirconium sponge, 163 tons of Zircaloy ingot and shapes, one-half ton of hafnium scrap; 5 tons of hafnium oxide; one-half ton of hafnium sponge and shapes; and 39 tons of hafnium crystal bar.

The Food and Drug Administration (FDA), insisting that the safety of zirconium-bearing compounds in antiperspirants has not been demonstrated, has proposed implementing a ban on the sale of these aerosol products. FDA officials were concerned that inhalation of the minute zirconium compound particles could cause chronic lung disease.[2] Although the ban has not yet taken effect and industry spokesmen continue to present scientific data confirming the safety of these products, reformulation of the products has been started reluctantly. The European Commission, studying the FDA report on banning zirconium compounds in deodorants, was contemplating proposals for governing their use in the community.[3]

DOMESTIC PRODUCTION

E. I. du Pont de Nemours & Co. and Titanium Enterprises, Inc., were the only major producers of zircon mineral concentrate in the United States. Zircon was recovered from mineral sands at the dredging and mining facilities owned by du Pont at Starke, Fla.; by Humphreys Mining Co. for du Pont, near Folkston, Ga.; and Titanium Enterprises at Green Cove Springs, Fla. Production data were withheld from publication to avoid disclosing individual company confidential data. The combined zircon capacity of these three plants is estimated to be 135,000 tons per year.

Humphreys Mining Co.'s new mining and wet-mill operations near Boulougne, Fla., were fully operational. The company's zircon dry mill was still located at Folkston. Du Pont completed its new facility for producing Zircore, its popular new low-cost zircon-aluminum silicate foundry sand. Titanium Enterprises' new dredge was performing up to expectations.

NL Industries, Inc., continued feasibility studies on recovering heavy minerals from the Trail Ridge Extension in Florida. NL planned to use a bucket-wheel floating suction dredge instead of the more conventional cutter-head type to facilitate mining in the indigenous hardpan. A decision on the project was expected by the end of 1976.

Ethyl Corp.'s plans for recovering heavy minerals, zircon, monazite, rutile, and ilmenite from deposits in the vicinity of Kentucky Lake in west Tennessee near Paris Landing in Henry County, was deferred until the markets for black sands improve. In spite of opposition by the press and environmental groups, Ethyl Corp. purchased additional land for the projected 2,000-acre mining area.[4]

Statistical data on production of zirconium sponge, ingot, and scrap and on hafnium sponge and oxide are also withheld to avoid disclosure of company confidential data. Approximately 2,300 tons of alloys containing from 3% to 70% zirconium was produced in 1975.

Three firms produced 30,080 tons of milled (ground) zircon, a decrease of 17% from the reported 1974 production. Six companies, excluding those that produce metal, produced 11,760 tons of zirconium oxide. Oxide production in 1975 rose slightly more than 1% over that reported in 1974.

Hafnium crystal bar, produced by two firms, was estimated at 30 tons, compared with 40 tons in 1974.

AMAX Specialty Metals Corp	Akron, N.Y	Sponge, crystal bar, ingot, scrap.
Do	Parkersburg, W. Va	Oxide.
Babcock & Wilcox Co., Nuclear Materials Div	Leechburg, Pa	Crystal bar.
Teledyne Wah Chang Albany Corp	Albany, Oreg	Oxide, sponge, crystal bar, ingot.

CONSUMPTION AND USES

Zircon consumption in the United States in 1975 was estimated at 122,000 tons. Consumption of zircon concentrate and milled zircon was 46,200 tons for foundries, 40,000 tons for refractories, 15,000 tons for zirconium oxide, 2,800 tons for zirconium alloys (excluding zirconium-base alloys), and 18,000 tons for all other uses. Foundries consumed approximately one-half of the domestic zircon production, with the remaining one-half consumed by refractory, abrasive, ceramic, metal, and other industries. Domestic zircon was marketed in proprietary mixtures for use as weighting agents, zircon-TiO_2 blends for welding-rod manufacture, and zircon-refractory heavy-mineral (kyanite, sillimanite, and staurolite) sand blends for foundry sand and sandblasting applications. The zircon-bearing foundry sand was reportedly designed to provide consistent high-quality performance at low cost for critical casting applications.

Imported Republic of South Africa baddeleyite ore in 1975 was used principally in the manufacture of alumina-zirconia abrasives and also in ceramic colors, refractories, and for other uses.

Preliminary Bureau of the Census figures for 1975 showed that shipments of zircon and zirconia brick and shapes, composed mostly of these materials, totaled 2.1 million brick, expressed in terms of equivalent 9-inch brick, valued at $16.7 million. In 1974, final figures for shipments were 2.7 million brick valued at $11.4 million.[5]

Zirconium metal was used in nuclear reactors, in chemical plants for corrosion-resistant material, in refractory alloys, and in photography for flashbulbs.

Zirconium compounds, natural and manufactured, were used in refractories, glazes, enamels, welding rods, chemicals, and sandblasting. Zirconium chemicals were finding increasing applications in the paint, textile, and pharmaceutical industries. Hafnium metal, alloys, and compounds continued to have few uses. The metal was used for nuclear reactor control rods, in special refractory alloys, and in photographic flashcubes. The nonnuclear hafnium metal uses were reportedly increasing.

Table 3.—Zircon consumption in selected zirconium materials as reported by producers in the United States in 1975

(Short tons)

Use	Quantity
Zircon refractories[1]	28,000
AZS refractories[2]	12,000
Zirconia[3]	15,000
Alloys[4]	2,800
Foundry aids	46,200
Other[5]	18,000
Total	122,000

[1] Dense and pressed zircon brick and shapes.
[2] Fused cast and bonded alumina-zirconia-silica-base refractories.
[3] Excludes oxide produced by zirconium metal producers.
[4] Exludes alloys above 90% zirconium.
[5] Includes chemicals, metallurgical-grade zirconium tetrachloride, sandblasting, and welding rods.

Table 4.—Zirconium oxide[1] consumption in selected zirconium materials as reported by producers in the United States in 1975

(Short tons)

Use	Quantity
AZ abrasives[2]	6,800
AZS refractories[3]	2,500
Other refractories	1,700
Chemicals	280
Glazes, opacifiers, and colors	480
Total	11,760

[1] Excludes oxide produced by zirconium metal producers.
[2] Alumina- and zirconia-based abrasives.
[3] Fused cast and bonded.

Table 5.—Yearend stocks of zirconium and hafnium materials
(Short tons)

Item	1974	1975
Zircon concentrate held by dealers and consumers excluding foundries	85,400	82,812
Milled zircon held by dealers and consumers, excluding foundries	6,500	4,721
Zirconium:		
Oxide [1]	1,480	1,745
Sponge	771	198
Ingot	507	38
Scrap	1,124	191
Alloys	178	851
Refractories	9,584	6,495
Hafnium: [e]		
Sponge	40	45
Crystal bar	10	11

[e] Estimate.
[1] Excludes oxide held by zirconium metal producers.

PRICES

Published prices for regular-grade domestic zircon remained unchanged at $257 per ton during the year. Foreign zircon also remained steady at nearly $600 per ton. Prices of zirconium oxides were either unchanged or unlisted for the entire year. The prices of zirconium chemicals and zirconium sponge, powder, sheet, and hafnium metal, sponge, and nitride were unchanged. The baddeleyite price, furnished by Ronson Metals Corp., advanced slightly during the year.

The Australian Department of Minerals and Energy at a November meeting reduced the minimum export price of zircon sand in bulk, containing 0.1% or more iron oxide (essentially West Coast material), from $A200 per metric ton to $A140 and $A150 per metric ton ($A1=U.S. $1.31) for material containing less than 0.1% iron oxide (East Coast material). The new prices apply to new contracts for standard grades of zircon for 1976 delivery. Premium-grade East Coast material, containing maximum 0.05% Fe_2O_3 and maximum 0.1% TiO_2, will sell at about $A10–20 per metric ton higher.[6] At the end of 1974, the spot price for standard-grade Australian zircon was around $A400 per metric ton free in Australian Container Depot (FID). Prices had risen rapidly in 1974 when a shortage developed because of a large increase in demand by the Japanese steel industry for zircon-bearing ladle refractories.

Table 6.—Published prices of zirconium and hafnium materials in 1975

Specification of material	Price
Zircon:	
Domestic, f.o.b. Starke, Fla. (Folkston, Ga.), bags, per short ton [1]	$257.00
Domestic, 75% minimum quantity zircon and aluminum silicates, Starke, Fla. (Folkston, Ga.), bulk, per short ton [2]	119.00
Imported sand, containing 65% ZrO_2, c.i.f. Atlantic ports, bags, per long ton [2]	560.00
Domestic, granular, 30-ton lots, from works, bags, per short ton [3]	$435.00– 440.00
Domestic, milled, 18-ton lots, from works, bags, per short ton [3]	490.00– 495.00
Baddeleyite imported concentrate:	
98% to 99% ZrO_2, minus 100-mesh, c.i.f. Atlantic ports, per pound [4]	.18– .25
99+% ZrO_2, minus 325-mesh, c.i.f. Atlantic ports, per pound [4]	.56– .72
Zirconium oxide:	
Powder, commercial-reactor grade, drums, from works, bags, per pound [3]	NA
Chemically pure white ground, barrels or bags, works, per pound [3]	2.22
Lump, electric fused, bags, 500- to 1,999-pound lots, from works, per pound [3]	NA
Lump, electric fused, bags, smaller lots, from works, per pound [3]	NA
Milled, bags, carlots, from works, per pound [3]	NA
Glass-polishing grade, ton lots, bags, 94% to 97% ZrO_2, from works, per pound [3]	1.11
Opacifier grade, 3,300-pound lots, 85% to 90% ZrO_2, bags, per pound [3]	.81
Stabilized oxide, 100-pound bags, 91% ZrO_2, milled, per pound [3]	1.57
Zirconium oxychloride: Crystal, cartons, 5-ton lots, from works, per pound [3]	.515
Zirconium acetate solution:	
13% ZrO_2, drums, carlots, 15-ton minimum, from works, per pound [3]	.22
22% ZrO_2, same basis, per pound [3]	.38
Zirconium hydride: Electronic grade, powder, drums, 100- to 990-pound lots, from works, per pound [3]	14.50– 16.00
Zirconium:	
Powder, per pound [5]	16.00
Sponge, per pound [2] [5]	5.50– 7.00
Sheets, strip, bars, per pound [2] [5]	10.00– 17.00
Billet bar, per pound [2]	8.00– 11.00
Hafnium:	
Sponge, per pound [5]	75.00
Bar and plate, rolled, per pound [5]	120.00
Nitrided, per pound [5]	34.25

FOREIGN TRADE

Exports of zirconium oxide increased in 1975 over those of 1974, but the exports of zirconium ore and concentrate declined. Exports of all forms of zirconium metal and alloys, in general, rose in 1975.

Zirconium ore and concentrate exported to 13 countries in 1975 decreased from 42,973,250 pounds valued at $3,323,134 in 1974 to 37,531,345 pounds valued at $4,786,799. The quantity exported decreased nearly 13% below that shipped in 1974, but the value rose over 44%. The 1975 value was an alltime high. The average value of the zirconium ore and concentrate exported in 1975 was $255.08 per ton; the 1974 value was $154.66 per ton. This increase was attributed more to the increasing value of zircon than to the larger proportion of higher cost granular and milled zircon shipped. The increase in the proportion of higher cost zircon shipped also indicates a return to the normal zircon-exporting pattern. The major recipients of exported zirconium ore and concentrate were the Netherlands (51%), Mexico (18%), Canada (14%), Brazil (10%), and Spain (5%).

Exports of zirconium oxide increased from 1,816,497 pounds valued at $1,534,010 in 1974 to 2,832,128 pounds valued at $2,905,711 in 1975. Export quantity rose 56% and the value 89% in 1975. These zirconium oxide shipments were made to 21 countries. The six major recipients in 1975 were France (44%), Canada (33%), Brazil and the United Kingdom (4% each), and Italy and Mexico (3% each).

Total exports of other classes of zirconium increased nearly 61%, from 1,650,695 pounds in 1974 to 2,649,694 pounds in 1975. The value of this material rose nearly 42% in 1975 to $25,828,888. Of the categories listed, zirconium and zirconium alloys, wrought, and zirconium and zirconium alloy foil and leaf increased in both value and quantity in 1975. The zirconium and zirconium alloys, unwrought and waste and scrap, decreased in both quantity and value in 1975. The wrought class increased approximately 50% in both pounds exported and in value, and exports of the foil and leaf class increased nearly fifteenfold in quantity and 69% in value. The unwrought and waste and waste and scrap class declined more than 50% in quantity.

Imports for consumption of zirconium ores in 1975 declined to 40,205 short tons, a 36% decrease compared with 62,504 short tons in 1974. The 1974 figure represents the lowest tonnage of ore imported since 1968 (59,900 tons). Zirconium ore imported from the Republic of South Africa is chiefly baddeleyite (ZrO_2) which, prior to 1974, was reported by the Bureau of Census under a separate category listing both quantity and value. This ore is now apparently imported under a blanket category which reports value only. It was estimated that approximately 1,200 short tons of South African baddeleyite was imported in 1975.

The average value of imported zirconium ores, mostly zircon, at foreign ports increased more than twofold in 1975 to $217.81 per short ton compared with $102.36 in 1974.

Imports for consumption of zirconium and hafnium in 1975 increased both in quantity and value in the following categories: Zirconium, wrought; zirconium alloys, unwrought; and zirconium, unwrought and waste and scrap. Imports for consumption decreased in quantity and value in the zirconium oxide category. In the remaining categories, zirconium compounds, n.e.c., and hafnium, wrought, the quantity imported decreased but its value increased.

WORLD REVIEW

Australia leads the world in production of zircon, which is recovered from sand-mining operations along the eastern coast (75%) and in Western Australia (25%). Production of zircon, a coproduct of rutile in the East, is expected to remain relatively constant due to lower grades and reserves coupled with persistent environmental problems. However, substantial zircon reserves with coproduct ilmenite have been located in Western Australia which, when fully developed, will assure Australia's continuing role in the world zircon markets.[7]

Zircon sand is also produced in Brazil, the People's Republic of China, India, Malaysia, the Republic of South Africa, Spain, Sri Lanka, Thailand, the Republic of Korea, and the U.S.S.R.

Baddeleyite is produced in the Republic of South Africa and Brazil; it is also found in east Africa, Sri Lanka, and the U.S.S.R.

[e] Estimate. [p] Preliminary. [r] Revised. W Withheld to avoid disclosing individual company confidential data.

[1] No data are available on production, if any, within the centrally-planned economy nations, nor is there any basis for the formulation of reliable estimates of output levels.

[2] Data is for fiscal year April 1, 1972, through March 31, 1973.

[3] Exports (production not officially reported; exports believed to closely approximate total output).

Argentina.—A Zircaloy tubing fabrication plant, being built in cooperation with the Canadian Government, was scheduled for operation in 1981 by Argentina's Comisión Nacional de Energía Atómica (CNEA).[8]

Australia.—A feasibility study for the country's first zirconia plant was being considered by Ionarc Smelters Ltd. of Vancouver, British Columbia, for Associated Minerals Consolidated Ltd. (AMC), a subsidiary of Consolidated Gold Fields Australia, Ltd. Ionarc uses a novel plasma, melting-leaching technique in its process for recovering the oxide. Zircon sand from existing leases was planned as feed for the plant. A decision on the new plant is expected early in 1976.[9] AMC also commissioned its new opacifier plant at Southport, 45 miles north of Brisbane. The plant was scheduled to grind zircon from the company's Dunwich operation on North Stradbroke Island. AMC was also working with the Australian steel industry and the Commonwealth Scientific and Industrial Research Organization (CSIRO) in developing and successfully testing a zircon ladle refractory for industrywide use.[10]

Mineral Deposits Ltd. (MDL) announced plans for starting up a 20,000- to 30,000-ton-per-year mineral sands operation, including zircon, at Agnes Water in central Queensland. Reserves were reported adequate for about 12 years at the announced rate.[11] MDL relocated its largest sand mining plant from Tuncarry to Bridge Hill Ridge North. The mineral sands plant, capable of processing over 1,500 tons per hour, was moved because of the New South Wales Government decision to allow mining only the northern section of the granted leases at Bridge Hill Ridge. The prohibition reduced the company's rutile and zircon reserves by 20% each. Reserves in 1974 were reported to be in excess of 1 million tons each.[12]

The beach sand mining project operated by D. M. Minerals, a joint venture owned by Dillingham Mining Co. of Australia Ltd. and Murphyores Holdings, Ltd., has started off the coast of Queensland on Fraser Island. The processing plant at nearby Maryborough, on the mainland, was almost complete. To date, approximately $10 million has been spent on development.[13]

Ferroalloy production, including ferrosilicon zirconium, was discontinued at the Broken Hill Pty. Co. Ltd. plant in Newcastle, New South Wales.[14] The plant was commissioned as a wartime measure in 1940.

Du Pont (Australia) Ltd. and Allied Minerals NL, partners in Allied Eneabba

Pty. Ltd., estimated their heavy-mineral reserves at 7.75 million tons of proven material and 27.75 million tons of probable ore. This $13.2 million beach sand project reached production stage in July.[15] The Jennings Mining Ltd., heavy mineral sands operation, also in Eneabba, about 180 miles north of Perth, reached design capacity during September.[16]

The Westralian Sands Ltd. proposed beach sand operation at Gingin was deferred along with the decision to establish an ilmenite beneficiation plant.[17] Western Mining Corp. Ltd. (WMC) bought all outstanding shares of Black Sands Ltd. (BSL), which owns deposits of heavy mineral sands north of Perth. In addition to $A5.15 million for the shares, $A3.62 million was allocated to repay money already spent on development work. An expected $A4.6 million was to be spent on further development. The Jurien deposits of BSL are said to contain 3.2 million tons of heavy minerals, including zircon, ilmenite, and rutile.[18]

A $22 million contract was awarded to Fluor Australia Pty. Ltd., a subsidiary of Fluor Corp., for engineering, procurement, and construction management of the Eneabba mineral sands project in Western Australia for Western Titanium Ltd., a subsidiary of Consolidated Gold Fields Australia Ltd. The project includes a mining facility with feed preparation, and wet and dry processing at Eneabba's port facility at Leeman. The dredging rate for the zircon, rutile, leucoxene, and ilmenite ore feed was under 700 tons per hour.[19]

Canada.—Norco Industries Ltd. started constructing its previously announced tube mill plant at Armprior, Ontario, to extrude zirconium alloy for fuel sheathing, zirconium alloy pressure tubes, and nickel and titanium alloys, as well as heat-exchange tubing. Production of nuclear-grade industrial tubing and zirconium alloys was scheduled for early 1976. Teledyne Wah Chang, Albany, Oreg., was to be the major supplier of the required zirconium alloys.[20] There currently is no commercial production of either zircon or zirconium alloys in Canada.

A promising source of future Canadian zircon was reputed to be the Athabasca tar sands currently being processed by Great Canadian Oil Sands (GCOS). The clean sands, high in zircon, in connection with the GCOS oil recovery program could supply up to 20,000 tons per year.[21]

Gambia.—A study to determine the technical, financial and economic feasibility of recovering zircon, ilmenite, and rutile from the mineral sands in the Brufut and other areas was being carried out for the Ministry of Economic Planning and Industrial Development by Matthew Hall Ortech of the United Kingdom.[22]

India.—Kerala Minerals and Metals Ltd. (KMM) Quilon, a heavy mineral sands producer on the Malabar Coast of the Arabian Sea, was involved in expanding its activities to include marketing refined mineral and chemical derivatives. The three-phase expansion program included a titania, titanium sponge, and zirconium chemicals plant.[23] A large, heavy-mineral sand deposit has been found in a 16-mile belt in the coastal areas of Ganjam and Puri districts in Orissa State on the Bay of Bengal, south of Calcutta, according to the Minister for Mining and Geology. The State Government had previously leased the deposit to Indian Rare Earths Ltd., a subsidiary of the Atomic Energy Commission of India.[24]

Malagasy, Republic of.—An Italian company, Montecatini Edison S.p.A., and United States Steel Corp. progressed on their exploration programs on the east coast for locating zircon and ilmenite deposits. Pilot plants were set up to determine the feasibility of commercial-scale production.[25]

Malaysia.—Trial runs for a new heavy-sand beneficiation plant near Ipoh, Perak, for the first half of 1976 was announced by Malaysian Trading, held by Straits Trading (30%) and two other Malay interests. Zircon production goals were not specified.[26]

Mauritania.—Proposed mining research for 1975–80, published by the Office of Mines and Geology, included heavy-mineral sandstone deposits in the south and in unspecified beach and dune zones.[27]

Mozambique.—The West German Institute of Geoscience and Raw Materials reported the discovery of an estimated 30 million tons of ilmenite, 2 million tons of rutile, and 3 million tons of zircon offshore under 98 to 165 feet of water. Preussag AG, a member of the West German AMR ocean mining group, was believed to have applied for a concession to explore the discovery.[28]

Peru.—A new mining company, Amautas Inc., working closely with the Government agency, Minero Perú, was studying the recovery of zircon, high-grade magnetite, and rutile from a stretch of beach sands in the north. The heavy minerals, intended for both local and international markets in 1976, were scheduled for export from the nearby ports of Paita and Talara.[29]

Philippines.—French interests have located large underwater placers of zirconiferous sand on the continental shelves.[30]

Senegal.—Tests conducted on beach sand samples from the coastal areas south of Dakar by the Ore Dressing Laboratory at Liége University in Belgium have yielded commercially promising zircon and titanium mineral concentrates.[31]

Sierra Leone.—Construction of a pilot plant, scheduled for completion in 1976, was announced by the Bayer-Preussag Mining group. The new group is essentially taking over where Sherbo Minerals Co. Ltd. ceased operating at Bonthe and Moyamba in 1971. Performance of the pilot plant, partially financed by the West German Government, will help determine whether the group, jointly owned by the Bayer Chemical Co. and Preussag, will commission a large-scale heavy-mineral separation plant.[32]

South Africa, Republic of.—The Richards Bay beach sand mining operation by Tisand Pty. Ltd., pending financial arrangements, was tentatively scheduled for operation by yearend 1977. Richards Bay Iron and Titanium Ltd. (RBIT) was responsible for titanium slag production. Tisand was backed by Union Corp. and Industrial Development Corp. (IDC); RBIT was backed by the Kennecott subsidiary, Quebec Iron and Titanium Corp. (QIT). Equity in the operating companies was Union Corp. (25%), IDC (25%), and QIT (50%).

Dredging capacity at Richards Bay was rated up to 96,000 tons per day with the annual production of over 150,000 tons of zircon. The company was planning to use Australian beach area reclamation consultants for guidance.[33]

Baddeleyite concentrates were produced at Phalaborwa, South Africa by Phosphate Development Corp. Ltd. (FOSKOR) and by Palabora Mining Co. Ltd. (PMC) mining contiguous deposits in the Palabora igneous complex. These baddeleyite concentrates, coproducts of copper, phosphate, and iron operations, pure (97% + ZrO_2) and ultrapure (99+%), were favorably received by the abrasive, ceramics, and refractory industries. Plant expansions are presently underway at both locations. In addition, PMC was producing and marketing an acid zirconium sulfate containing 33.1% ZrO_2.[34]

Spain.—Two new zircon grinding and opacifier plants were under construction and due for completion in 1976. Associated Lead Manufacturers' (ALM) plant is at Valencia and Vicor Quimia S.A.'s plant is at Tarragona. The latter plant has a capacity of 17,000 short tons per year.[35]

Sri Lanka.—An expansion program was begun by Mineral Sands Corp. of Sri Lanka, a producer of ilmenite and rutile, to include zircon-recovery circuits. The program also involved moving operations from China Bay, Trincomalee, to Pulmoddai where work has already started on the new mineral sands plant. This plant is due to come onstream by 1980.[36]

Yemen, People's Democratic Republic.—A recently completed survey oulined large reserves of zircon and titanium-bearing minerals in the beach sands in the Maabir-Gaabar area southwest of the port of Mukalla.[37]

TECHNOLOGY

Bureau of Mines research efforts were directed toward using zircon as mold material for metal casting, electrolytic preparation of zirconium and hafnium diborides, advanced zirconium alloys, and an electron microprobe study of commercially available zircons. Preliminary tests on a shell-casting process for titanium indicate the potential use of zircon sand and waterglass binder. Results on molybdenum casting have shown that molds of suitable strength can be made by using zirconium and aluminum oxides bound with zirconium acetate and fired in either air or hydrogen. In the electrolytic research, zirconium and hafnium diborides of approximately 98% purity were electrodeposited from their respective oxides dissolved in borate-cryolite-carbonate electrolytes at 1,050° C.[38] Zirconium diboride was also deposited from an electrolyte prepared with zircon sand. Microprobe studies on zircon revealed that an appreciable portion of the yttrium, rare earth, and phosphorus are in solid solution, and only a part of these impurities could be removed from these concentrates by mineral-dressing techniques.[39] Magnetic zircon grains contained considerably more yttrium and phosphorus, presumably as a xenotime (YPO^4) solid solution, and frequently bore xenotime and apatite precipitates or inclusions. Continuous chlorination of zircon in the initial step of zirconium sponge production has resulted in the deleterious carryover of rare earth and phosphorus impurities. The rare earths adversely affect the thermal neutron cross section and phosphorus lowers the corrosion resistance of the fabricated zirconium product. Initial Bureau testing on advanced alloys demonstrated that a commercial magnesium-zirconium alloy displayed superplastic behavior under certain combinations of microstructure, temperature, and strain rate. Superplasticity or exaggerated ductility could conceivably permit the solid-state injection molding of intricate shapes. In other work, the creep behavior of a tungsten alloy strengthened by a ZrO_2 dispersoid was studied over a range of temperature and stress conditions.[40] A "sandwich panel" developed by Bureau metallurgists has promise in turning more of the sun's rays into heat for making steam.[41] The panel consists of zirconium sputtered in thin layers on copper and silver and then chemically converted to zirconium oxide or nitride. Zirconium subnitride on silver was the most effective combination in absorbing the rays and converting them into heat. The silver or a copper backing carries the heat away by conduction for use in making steam for electric power and other purposes.

A report on the heavy mineral placers in the southeastern Atlantic States, with particular emphasis on the general geology of the Piedmont and Coastal Plain Provinces, along with a detailed description of past and present placer mines in South Carolina, Florida, and Georgia was published.[42] The mineralogy of the potentially valuable zirconiferous beach sands near Cox's Bazar, about 62 miles south of

Chittagong on the southern coast of Bangladesh, was discussed.[43] A report on the Eneabba deposits of western Australia operated by Jennings Mining Ltd., its dry and wet mills, their capacities, and marketing plans were outlined.[44] Present and future supply-demand technical relationships for zircon and South African baddeleyite were documented.[45] Predictions of a zircon oversupply and a fall in prices were presented. The prediction was based on the substitution of alternative foundry and refractory materials, such as chromite and olivine. Another work also predicted technologic trends resulting in changes of zircon supply and demand patterns for the middle 1970's.[46]

An improved method was patented for beneficiating oxide ores, such as baddeleyite, by froth flotation.[47] The improved process requires conditioning the comminuted ore slurry with an inorganic peroxyacid or their alkali or ammonium salts, followed by an effective amount of a collector/frother of an alkyl-olefin adduct of glycerol-type compound. Another patent now enables chrome fungicidal mineral dyeing from a single zirconyl acetate system, without the need for an alkali.[48] Previously, separate baths were required to deposit the dye and fungicide on cellulosics. A new additive system for quicker drying alkyd coatings, based on a low acid calcium primary dryer and a cobalt-zirconium auxiliary dryer, was announced.[49] A depletion of zirconium was noted in fly ashes downstream from mechanical collectors.[50] This depletion was attributed to the occurrence of zircon, the source of zirconium in coals, which does not combine readily with lithophile minerals and melts at a very high temperature. The high melting point would preclude glassy sphere formation during coal burning which comprises the bulk of fly ash. In addition, zircon has a higher specific gravity (4.6) than fly ash (—2.5) and is resistant to mechanical breakage. A similar study of some Belgian coals and ashes, analyzed for 44 elements using a combination activation analysis with thermal and 14-MeV neutrons, was also published.[51] A method for the spectrophotometric determination of hafnium in the presence of zirconium was developed.[52] This method is one of few known that permits the ready determination of hafnium in the presence of zirconium.

A highly accurate method for monitoring water vapor concentration in a hydrogen atmosphere or trace amounts of hydrogen in water vapor is now possible with a newly developed solid stabilized zirconia electrolyte technique.[53] The new method is based on a commercially available zirconia tube with one closed end. The closed end protrudes into the atmosphere being measured, heated from 500° to 600° C, and monitors the gas as it is passed over the hot tube. The new system easily measures from several parts per million to several parts per 100 million. Lanthanum-doped lead zirconate-titanate ceramics (PLZT) and similar materials (Pb, La, Hf, Ti, O_3) that have potential for electrooptic applications because of their high transparency and good electrooptic characteristics, can now be fabricated.[54] The new fabrication method uses ferroelectric materials with small anisotropy to insure highly transparent ceramics. The anisotropy of these materials was further controlled during hot-pressing by changing the Sr- or Ba-doping concentrations. The influence of grain size on the optical properties of PLZT ceramics were measured and correlated with optical transmission at various wavelengths.[55]

Satisfactory performance of modified PZT piezoelectric ceramic disks was reported for a wide range of hydrostatic pressures and electric fields.[56] The solubility limit of lanthanum in PLZT systems was established in conventionally sintered ceramics by the disappearing-phase technique using X-ray diffractometry.[57] Changes in slope of the lattice constants and stabilization of the Curie temperature were used as independent checks on the disappearing method.

Partially stabilized zirconia (PSZ) products that are both stronger and more resistant to thermal shock than either unstabilized or fully stabilized bodies were found to be superior because of the fine dispersion of zirconia precipitates in the cubic grains.[58] The transmission electron microscopic studies revealed that the useful mechanical properties of PSZ result from the influence of these tetragonal precipitates on crack propagation. The high-temperature creep behavior of yttria-stabilized zirconia (YSZ) was studied at temperatures to 1,200° C under the conditions of stress and environments found in storage heaters in "blow down" wind tunnels.[59] This research is invaluable in predicting the plastic deformation of YSZ which is related to its structural integrity, during the operation of storage heaters. The anticipated useful and unique plastic behavior of hot-working ZrO_2 during its monoclinic-to-tetragonal inversion was not realized.[60] Although this behavior did not occur, light was indeed shed on the phenomenon of "transformational plasticity" in ZrO_2.

A reexamination of ternary system CaO–ThO_2–ZrO_2, using induction plasma torch techniques, discovered a new pyrochlore-type compound with the approximate composition of 2 CaO–2ThO_2–5ZrO_2.[61] Phase equilibria in the yttria-hafnia system were investigated by high-temperature and room-temperature X-ray diffractometry.[62] The HfO_2 transformation, solid solution limits, liquidus temperatures, and a tentative phase diagram were advanced. Hafnia is a promising refractory material. Success was also noted with ZrO_2 ZrN, and ZrC additives. The effects of impurities on these mechanisms are presently being investigated.

Zirconium alloy oxidation was attributed to a cubic rate law, but the actual kinetics depended on the exact relationship between grain diameter and film thickness.[63] The diffusion of oxygen in zirconium was determined by nuclear microanalysis techniques.[64] A unique profile of the oxide penetration was readily apparent.

Studies on ternary molybdenum-based alloys, some of which contain hafnium as the hardening agent, showed that this hardness behavior can be anticipated from binary data with an expression involving the number of s + d electrons contributed by the solute elements.[65] If this argument is valid, it should be possible to simply predict the hardness behavior of ternary alloys. An alternative expression explaining alloy softening was also offered.

Steel pipes capable of handling molten metal were manufactured by protecting them with a layer of zirconium nitride.[66]

Materials for nuclear power systems, including zirconium alloys, were listed in a guide planned for use in various commercial and development systems.[67]

Porous platinum layers formed on the inner and outer surfaces of ceramics, such as zirconia, serve as electrodes and also perform a catalytic function. However, the nonadherence of the platinum layers after exposure to reducing atmospheres at high temperatures has limited its applicability.[68] This debonding or nonadherence was attributed to the reaction between platinum and the zirconia, which form either solid solutions or intermetallic compounds. This mechanism was also observed for the cubic stabilizer as well as for the SiO_2 impurity present in ZrO_2. A grain stabilized zirconia product with platinum was experiencing increased use as a replacement for platinum and its alloys in high-temperature service in oxidizing atmospheres.[69] Preliminary research was successful on hot-pressing Si_3N_4 using zirconium-bearing additives such as zircon to promote densification and form a more refractory silicate grain-boundry phase, thereby improving high-temperature strength.[70]

ARSENIC[1]

Legislation and Government Programs.—The Occupational Safety and Health Administration (OSHA) held public hearings in early 1975 on proposed standards for exposure to inorganic arsenic. The findings obtained at the hearings will be considered to promulgate emission standards.

Domestic Production.—Arsenic trioxide (As_2O_3) was produced domestically only at the Tacoma, Wash. copper smelter of ASARCO Incorporated. Production data cannot be published. Output rose 9% over that of 1974, shipments were less than half those of 1974, and stocks rose 31%. Production of arsenic metal, begun by ASARCO in August 1974, continued in 1975.

Consumption and Uses.—Apparent consumption of arsenic, essentially all as white arsenic (As_2O_3), was substantially lower than that used in 1974. Data for calcium and lead arsenate, historically the principal end products, cannot be published.

The use of chromated copper arsenate (CCA compounds) in wood preservatives increased for the seventh consecutive year; 7,629 tons, 31% more than that in 1973, was consumed in 1974. Consumption of fluor chrome arsenate phenol (Wolman salts and osmosalts continued downward; 758 tons was consumed in 1974 compared with 842 tons in 1973.

Small quantities of high-purity arsenic were used in the manufacture of gallium and indium arsenides for semiconductors.

Prices.—The price of refined white arsenic, 99.5%, at New York docks, was quoted at 20 to 23 cents per pound throughout 1975. Refined white arsenic at Laredo was raised from $210 per ton at yearend 1974, to $300 per ton in early January 1975, and to $330 per ton on September 18. The price of arsenic metal at Tacoma was quoted at $3,200 per ton throughout 1975.

Arsenic metal was quoted in London at £1,500 to £2,000 per metric ton until May 7 when it rose to £2,175 per metric ton where it remained throughout 1975.

Foreign Trade.—Imports of white arsenic dropped 13% from those of 1974 and were the lowest since 1960. Sweden remained the principal supplier accounting for 60% of the total receipts. Mexico provided 26%, South West Africa 8%, France 5%, and the remainder came from West Germany, Peru, and Switzerland. All of the arsenic acid (26 pounds)came from Belgium-Luxembourg, 52 pounds of arsenic sulfide was received from the United Kingdom, and 1,323 pounds of sodium arsenate came from West Germany. Of the 152,496 pounds of other arsenic compounds imported in 1975, 111,146 pounds came from the United Kingdom, 40,807 pounds came from Switzerland, 536 pounds came from West Germany, and several pounds each came from Belgium-Luxembourg and Japan.

---

[1] Prepared by Gertrude N. Greenspoon, mineral specialist.

Arsenic metal imports totaled 483 tons, 32% less than those of 1974. Sweden supplied 463 tons, Canada 18 tons, and West Germany and Japan each 1 ton. Smaller quantities were received from the United Kingdom, the Netherlands, and Belgium-Luxembourg.

Arsenic compounds, n.e.c	(1)	21	85	55	152	90

[1] Less than ½ unit.

Tariff.—Arsenic oxide (white arsenic) enters the United States duty free. A 1.2-cent-per-pound duty was applicable to arsenic metal.

World Review.—*Philippines.*—The first phase in the construction of a copper smelter and refinery by Lepanto Consolidated Mining Co. will be a roasting plant. Lepanto reportedly has not been able to dispose of all the concentrates it produces because of the high arsenic and antimony contents. The new plant, expected to be operational in 1978, will enable the company to recover 8,800 tons of arsenic annually.[3]

Sweden.—Production of white arsenic and arsenic metal by Boliden Aktiebolag were lower than in 1974 as work continued on developing processes for improving the environment.

[1] Including calculated arsenic trioxide equivalent of output of elemental arsenic and arsenic compounds other than white arsenic, where inclusion of such materials would not duplicate reported white arsenic production.

[2] In addition to the countries listed, Austria, Belgium, the People's Republic of China, Czechoslovakia, East Germany, Finland, Hungary, Southern Rhodesia, the United Kingdom, and Yugoslavia have produced arsenic and/or arsenic compounds in previous years but information is inadequate to ascertain whether such production has continued or not, and if so, at what levels.

[3] Output of Tsumeb Corp. Ltd. only.

Technology.—A treatment process to remove heavy metals from waste waters has been used commercially in Japan since 1974. The selective adsorbents sold by Nippon Soda Co. (Tokyo) exhibit an excellent affinity for arsenic and other heavy metals.[3]

CESIUM AND RUBIDIUM[4]

Domestic Production.—There was no domestic production of cesium- or rubidium-bearing minerals during 1975. *ALKARB,* a residue from the processing of lithium ores in previous years, and imported lepidolite were the source of domestically produced rubidium and its compounds.

Total production of cesium chemical compounds increased about 30% in 1975, while production of rubidium chemical compounds declined about 15% compared with 1974 levels.

The following companies produced cesium and rubidium chemicals during the year: Great Western Inorganics, Inc., Golden, Colo.; Kawecki Berylco Industries, Inc., Revere, Pa.; and Kerr-McGee Chemical Corp., Trona, Calif. No production of cesium and rubidium metal was reported, but small quantities of both metals were shipped from stocks.

Consumption and Uses.—Data pertaining to consumption and end use distribution of cesium and rubidium metals and compounds were not available. These materials found commercial application in the manufacture of pharmaceuticals, ultracentrifuge separation of organic compounds, and electronic apparatus such as scintillation counters, photomultiplier tubes, and photoelectric cells. Cesium, rubidium, and their compounds can be substituted for each other in some end uses.

While there were no large-scale commercial uses for cesium, cesium metal and compounds have been used in experimental magnetohydrodynamic (MHD) power generators. If MHD electrical generation is successfully developed, demand for cesium may increase in the future.

Prices.—The American Metal Market quotation on cesium metal, 99+% purity, remained unchanged at $100 to $375 per pound. The quotation on rubidium metal, 99.5% purity, also remained unchanged at $300 per pound until the American Metal Market ceased publishing the price early in 1975. At yearend the Metal Bulletin quoted the nominal price for pollucite concentrates containing a minimum 24% Cs_2O, f.o.b. source, at $12.40 to $13 per metric ton unit (22.046 pounds of Cs_2O).

Source: Kawecki Berylco Industries, Inc.

Foreign Trade.—Pollucite import data were not available. However, reported receipts by consumers indicated that pollucite was imported. Most of the pollucite consumed in the United States came from Canada.

Imports of cesium compounds decreased from 4,622 pounds valued at $167,965 in 1974 to 3,156 pounds valued at $136,203 in 1975. No cesium or rubidium metal were imported during the year.

Table 5.—U.S. imports for consumption of cesium compounds in 1975, by country

Country	Cesium chloride		Cesium compounds, n.s.p.f.	
	Pounds	Value	Pounds	Value
Canada	--	--	[1]113	$5,169
France	44	$1,307	--	--
Germany, West	1,039	52,041	1,894	75,681
United Kingdom	55	1,684	11	871
Total	1,138	55,032	2,018	81,171

[1] Estimated by Federal Bureau of Mines.

World Review.—During 1975, the Tantalum Mining Corp. of Canada, Ltd. shipped 747,279 pounds of pollucite containing 23.2% Cs_2O from its Bernic Lake, Manitoba, Canada, property; 554,096 pounds were exported to the U.S.S.R., 191,010 pounds to the United States, and 2,173 pounds to Japan.

Technology.—The U.S. Energy Research and Development Administration (ERDA) continued to sponsor joint U.S.–U.S.S.R. MHD research. A Soviet 1-megawatt MHD generator using U.S.-built power electrodes operated continuously for 127 hours. The United States and the U.S.S.R. were building a 25-megawatt MHD generator near Moscow.

In the United States, ERDA awarded a $3.5 million contract to Avco Everett Research Laboratory for coal-fired MHD power generation research. A $50 million MHD research facility will be constructed at Butte, Mont.

The geochemical dispersion of rubidium and strontium together with alteration studies could be used in defining areas suitable for detailed copper exploration.[5]

[5] Olade, M. A., and W. K. Fletcher. Primary Dispersion of Rubidium and Strontium Around Porphyry Copper Deposits, Highland Valley, British Columbia. Econ. Geol., v. 70, No. 1, January–February 1975, pp. 15–21.

GERMANIUM [6]

Consumption of germanium has not changed significantly since 1970. In 1975, the use of germanium in transistors continued to decline, but increasing use in light-emitting diodes and in infrared optical applications compensated for this loss.

Domestic Production.—The primary portion of U.S. germanium output was derived from smelter residues stockpiled in past years from the treatment of zinc concentrates from the Kansas-Missouri-Oklahoma zinc district and the southern Illinois fluorspar-zinc-lead district. This primary production was supplemented by the recovery of secondary material from waste and new scrap generated from the manufacture of electronic components and the cutting of semifabricated shapes.

Eagle-Picher Industries, Inc., of Quapaw, Okla., was the sole primary producer in 1975. Other producers of germanium using imported metal, oxide, scrap, and domestic secondary materials were Kawecki Berylco Industries, Inc., Revere, Pa.; Atomergic Chemetals Co., Carle Place, N. Y.; and Texas Materials Laboratory, Garland, Tex.

Domestic germanium production in 1975 was estimated to be 30,000 pounds, supplying about two-thirds of U.S. demand. The value of domestic production would be about $4 million based on the producer price.

Consumption and Uses.—The decline in use of germanium in transistors in 1975 was accentuated by the general slackening of business activity. The increased use of germanium in light-emitting diodes for minicomputers and digital watches, and the continued development of optical systems for infrared detection instruments more than compensated for the decreased use in transistors. The estimated distribution of consumption by classes was: Instruments 50%, electronics 46%, and others 4%. Included in the broad category of instruments are forward-looking infrared devices (FLIR), nuclear radiation measuring devices, wide-angle camera and microscope glass lenses, X-ray equipment, fluorescent lamps, and strain gages. Other uses included alloys for brazing and soldering materials, experimental catalysts for petroleum refining, and biological uses based on organogermanium compounds. Projects under research or development require small amounts of germanium, and include experiments producing columbium-germanium films that are superconductive up to 23° K, and the use of soluble germanium compounds to reduce the internal resistance of lead-acid storage batteries.

[6] Prepared by John M. Hague, mining engineer.

Prices.—The U.S. producer prices for zone refined germanium and domestic germanium dioxide have been $293 per kilogram and $167.50 per kilogram, respectively, since June 8, 1970. Prices for imported germanium, quoted as a New York dealer price in Metals Week, were increased March 3, 1975, to $330 per kilogram for metal and $174.50 for germanium dioxide. The previous prices were $275 and $145.50 per kilogram, respectively.

Foreign Trade.—U.S. imports of germanium metal (unwrought, and waste and scrap) increased 20% in quantity in 1975, to 16,900 pounds valued at $1,561,000. Imports came from the U.S.S.R. 50%, West Germany 37%, Japan 4%, the Netherlands 4%, with Belgium, the United Kingdom, and Italy providing the balance.

Table 7.—U.S. imports for consumption of germanium in 1975, by country

Country	Quantity (pounds)	Value
Unwrought, and waste and scrap:		
Belgium-Luxembourg	492	$470,428

Czechoslovakia	22	1,617
Total	24	2,560

World Review.—A principal source of germanium in recent years has been the Kipushi mine in Zaire. Mine production was 136,000 pounds in 1974, and was forecast as 140,000 pounds in 1975. The production of Zaire is refined in Belgium.

The Tsumeb mine in South-West Africa for many years has been a source of germanium; its production was recovered from a blister copper product refined in West Germany.

Japan produced both germanium oxide and metal in 1975, for a total output of approximately 34,000 pounds. The sources of Japan's germanium production are thought to be zinc concentrates, secondary materials, and flue dusts from germanium-bearing coals.

World production of germanium in 1975 was estimated to be in the range of 250,000 to 300,000 pounds (110,000 to 135,000 kilograms).

Technology.—A new method of fabricating light-emitting diodes was developed using a germanium substrate with a gallium arsenide phosphide epitaxial layer.[7]

Interest continued to grow in infrared photography and optics for defensive and night-fighting systems known as FLIR.

The antimicrobial properties of organogermanium compounds have promoted investigations into their pharmacological uses.[8]

The reaction of germanium with germanium dioxide to form and sublimate germanium monoxide was studied as a means of eliminating the oxygen present in germanium.[9]

INDIUM [10]

Domestic Production.—Indium was produced during 1975 by ASARCO, Inc. at its Denver, Colo. plant and by Indium Corp. of America in Utica, N.Y. Indium products were made from domestic and imported zinc concentrates, and from residues or bullion forwarded from other smelters. Other U.S. companies processed or refined imported materials to produce alloys, compounds, or high-purity metal components. Domestic production was estimated to exceed imports in 1975, with other substantial contributions to supply coming from industry stocks and from secondary or scrap materials. In April, ASARCO announced that indium production was being phased down at its Denver plant because of lack of suitable indium-bearing zinc ores. Some intermittent production was to be continued for as long as 2 years. Customers were to be serviced through inventories.

Consumption and Uses.—The demand for indium was much lower in 1975 than in preceding years, but the rate of consumption increased toward yearend. While the use in electronic components continued to decline, the use in alloys, solder, and coatings continued to grow slightly, but overall consumption was estimated to be about 30% below that in 1974. The pattern of indium usage in 1975 was divided roughly as 9% in electronic components, 44% in solders, low-melting alloys and coatings, 27% in instrument applications and holding devices, and 20% in research and other uses including nuclear reactor controls.

Stocks.—Producer stocks were estimated to have declined during 1975, and combined stocks of metal compounds and material in process at yearend were thought to be of the order of 1 year's supply.

Prices.—Indium prices are based on the standard-grade metal, 99.97% pure. Higher purity grades, 99.999% indium or better, are available at a premium. The quotation published in Metals Week is for ingots, usually of 100 troy ounces, in lots of 10,000 ounces or more. This quotation was $5.50 per ounce from January to April 1975, at a range of $5.50 to $6.15 per ounce until September, and $6 per ounce for the balance of the year. The average U.S. price in 1975 was $5.80 per ounce. The quotation in Metal Bulletin (London) was $5.50 per ounce in January and $6 for the remaining 11 months of 1975.

Foreign Trade.—Imports of indium declined sharply from the record high of 811,500 ounces in 1973, and 493,000 ounces in 1974, to 113,800 ounces in 1975. The value of imports in the 3 years was $986,000 in 1973, $1,906,000 in 1974, and $629,000 in 1975. West Germany, Japan, Peru, the United Kingdom, and Canada were the principal sources of supply, with Canada showing the greatest change from major supplier in 1973 to a minor source in 1975.

The duty on unwrought, waste, and scrap indium has been 5% ad valorem since January 1, 1972 for the most favored nations. Duties on waste and scrap have been suspended until June 30, 1978. The duty on wrought indium has been 9%. Statutory duties for the U.S.S.R. and East Germany were 25% ad valorem on unwrought indium and 45% ad valorem on wrought metal.

---

Technology.—Research was continued on the development of solar cells using indium compounds, the use of indium in photodetector and infrared detector devices, and the employment of indium as a sealant between glass and metal surfaces.

Light-emitting diodes of indium, gallium, and arsenic were employed in methane detecting devices under development by the Bureau of Mines.[11]

RADIUM[12]

The major use for radium was in therapeutic treatment of cancer. Replacement of radium by other radioisotopes continued.

Domestic Production.—There was no reported radium production in the United States during 1975. Imports, withdrawals from company stocks, and reprocessing, supplied sufficient radium to meet the small domestic demand. Radium Chemical Co., Inc., N.Y., was the main domestic dealer.

Consumption and Uses.—Radium was mostly used in the therapeutic treatment of cancer. A few tens of millicuries of radium were consumed in the production of home alarm smoke detectors. Other uses of radium were as a source of gamma radiation, used in soil moisture density gages, and in static eliminators, although polonium-210 was replacing radium. One traditional use of radium, as an illuminator on alarm clocks, was replaced by tritium.

About 900 grams of radium was used in the United States, and around 93 grams was stored in a Government-depository in Alabama during 1975. About 77 requests for deposits containing a total of 5,800 milligrams of radium were received by the Bureau of Radiological Health, U.S. Department of Health, Education, and Welfare.

Prices.—Radium prices, per milligram unencapsulated, were quoted by Radium Chemical Co., Inc. as follows: Less than 100 milligrams, $26.50; 100 to 199 milligrams, $25; 200 to 499 milligrams, $22; over 5 grams, $20. There was no increase from the 1974 prices.

Foreign Trade.—Official trade statistics did not report trade in radium, as such, but included radium with other radioactive commodities. Belgium remained the principal source of imported radium.

BuMines Open File Rept. 78–75, 1974, 69 pp.; available for consultation at the Bureau of Mines libraries in Pittsburgh. Pa., Denver, Colo., Spokane, Wash., and Twin Cities, Minn.; at the Energy Research and Development Administration library in Morgantown, W. Va.; and at the Central Library, U.S. Department of the Interior, Washington, D.C.

[12] Prepared by Rebecca P. Smith, physical scientist.

World Review.—Information on radium in world markets was not readily available. The largest radium producer and supplier was the Belgian company, Union Minière S.A. Small quantities of radium were also apparently produced in Canada, in the United Kingdom, and in some centrally controlled economy countries. The industrial nations consumed most of the radium in use patterns similar to those of the United States.

Technology.—During uranium extraction nearly all the radium remains in the mill tailings, causing storage and possible environmental problems. Laboratory tests found several methods for more effective removal of the radium—separation of the slimes, which contain most of the radium, from the sand fraction, and leaching with solutions of either hydrochloric acid or ethylenediamine tetraacetic.[13]

The U.S. Environmental Protection Agency was studying potential health hazards of radioactive uranium tailings. In at least one locality, radioactive material (primarily radium) had already experienced extensive migration from the original tailings piles.

A technique for uranium prospecting was described. Radium in soil was measured by analyzing for the emitted daughter radon. Comparisons of soil radium over specific uranium occurrences were given. Advantages of this method are that results can be obtained on site, equipment is simple, and results are reproducible.[14]

SCANDIUM[15]

Minor quantities of scandium were consumed during 1975, mostly in research applications. There was no mine production of scandium, and imports and industrial stocks were sufficient to meet domestic demand. One domestic producer provided the majority of the scandium metal and compounds consumed.

Domestic Production.—In 1975 there continued to be no domestic mine production of scandium. There were two major producers of scandium metals and compounds, Research Chemicals, a division of Nucor Corp., Phoenix, Ariz., supplying about 90% of the domestic demand, and Atomergic Chemetals Corp., Plainview, N.Y. During 1975 there was a slight increase in the demand for scandium products, although this demand still totaled only a few tens of pounds.

Consumption and Uses.—Research and development continued to be the major consumer of scandium. In addition, there were three main industrial uses. High-purity scandium metal was a component in special high-intensity mercury vapor lamps used for providing outdoor lighting for events televised in color. These lamps emit an illumination approaching the quality of sunlight. Small quantities of scandium were used to strengthen magnesium alloys and scandium-46 was used for tracing underground fluid flows in petroleum production. Some scandium was consumed by the chemical and electronic industries.

Prices.—During 1975 the price of scandium metal and compounds remained stable at the 1974 levels quoted by Research Chemicals that are shown below. Scandium was also available in sheet foil of 0.001 to 0.1 inch thick at $22 to $105 per square inch in 1- to 10-square-inch lots.

Metal	Per gram, from 1 to 99 grams	Per gram, from 100 to 453 grams
Ingots	$10.50	$8.00
Powder	11.50	10.35
Chips	11.50	10.35
Distilled	19.00	15.00
Oxide:		
99.99%	5.00	4.00
99.9%	3.50	2.80
Salts [1]	2.50	2.00

[1] Salts include acetates, carbonates, chlorides, nitrates, and oxalates in most stable, hydrous form produced from oxides of 99.9% minimum purity.

Foreign Trade.—There were no official U.S. trade statistics for scandium. Scandium was included in the other minerals and metals category, however, scandium trade is believed to be minor. Based on available information, Australia and centrally controlled economy countries were the principal suppliers of scandium-bearing raw materials.

[15] Prepared by Rebecca P. Smith, physical scientist.

World Review.—Information on scandium-related activities in foreign countries was not readily available. The industrialized nations were involved in scandium research and used small quantities of scandium in industrial applications.

Technology.—A book discussing the technology, applications, occurrence, and chemistry of scandium was published.[16]

An improved terbium activated lutetium-yttrium silicate phosphor contained small quantities of scandium which increased the luminosity of the phosphor about 10% when excited with an electron beam.[17]

Films of yttrium and scandium on stainless steel substrates were tested as an improved radioactive source of electrons over thin films of titanium tritide. The limit of thermal stability was higher, with good adhesion and resistance abrasion properties.[18]

In another research project, a scandium filter that views a manganese scatterer was developed to produce a pure 2-kev beam in the National Bureau of Standards reactor. Details of the filter construction and the use of titanium with scandium to reduce the background were discussed.[19]

SELENIUM [20]

Domestic production of selenium from primary materials was 357,700 pounds in 1975, a 44% decrease from the 1974 production of 644,000 pounds.

Shipments by domestic producers decreased 58% to 284,400 pounds in contrast to the record high level of imports of 889,300 pounds of selenium. Producer stocks increased 93% over yearend 1974 stocks to 152,400 pounds at the end of 1975. The sharp drop in production and shipments and the continued increase in imports were attributed to four main factors: A recession-generated 32% drop in apparent consumption, the operating of the U.S. copper industry at approximately 30% below capacity, the closing down of one major selenium refinery and the initial phasing out of a second refinery, and competition from low selenium dealer prices. Led by Japan, world production increased 7% to 2.5 million pounds.

Legislation and Government Programs.—On December 24, 1975, the Environmental Protection Agency (EPA) enacted the National Interim Primary Drinking Water Regulations which set the maximum contaminant level for inorganic selenium in community water systems at 0.01 milligram per liter.[21]

During 1975, the General Services Administration (GSA) shipped 6,100 pounds of selenium. The GSA held 2,500 pounds of selenium at yearend.

Domestic Production.—In the United States in 1975 primary selenium was recovered at four copper refineries, AMAX Copper, Inc., Carteret, N.J.; ASARCO Incorporated, Baltimore, Md.; Kennecott Copper Corp., Magna, Utah; and The Anaconda Company, Perth Amboy, N.J.

In addition, anode slimes recovered from the electrolytic tanks of copper refineries owned by other foreign and domestic mining companies were shipped to these plants for recovery of gold, silver, selenium, and tellurium.

High-purity selenium and various selenium compounds were produced by primary and other processors from commercial-grade metal.

The Anaconda Company permanently closed its 77-year-old Perth Amboy refinery in April 1975 owing to general economic conditions adversely affecting the copper industry and to a lack of refinery feed material, formerly obtained from Anaconda's expropriated mines in Chile. ASARCO began preparing for the phaseout of its Baltimore plant in conjunction with the startup of a byproduct recovery plant at the new Amarillo, Tex. copper refinery in early 1976. The Wittenzellner Refinery Co., an associate company of the A. J. Oster Co., reported the startup in April, on a limited basis, of a new refinery in Providence, R.I. employing a unique selenium recovery process.

Data on actual recovery by domestic secondary refineries were not available but was estimated at around 10,000 pounds in 1975, reflecting the shortage of electronic scrap due to impact of the substitution of silicon for selenium in the rectifier market. Additionally, up to 175,000 pounds of secondary selenium may be processed in U.S. and Canadian refineries, principally from the recycling of selenium-bearing elements in photocopying machines used in the U.S. market.

Consumption and Uses.—Apparent consumption of selenium in 1975 consisting of shipments from primary producers, net imports, and stockpile releases decreased 32% to 1.06 million pounds. However, apparent consumption during the fourth quarter, increased to over twice the average for the first three quarters, and appeared to signal a turnaround in the weak selenium market. The reduced demand for selenium-bearing materials such as glass, pigments, specialty steels, and electronic components generally mirrored the impact of the 1974–75 recession on construction and manufacturing activity in the U.S. economy during this period. Trends in 1975 suggested the following estimate of selenium purchases and consumption by end-use categories: Electronic components including xerography, 41%; glass manufacturing, 28%; chemicals, 19%; and other, 12%.

Consumption of primary metal in the copier and duplicator market dropped slightly in 1975 although total usage increased owing to the growing contribution of recycled selenium home scrap. Competition in the duplicator market reportedly will increase following the July 29, 1975, U.S. Federal Trade Commission issuance of a consent order settling its antitrust complaint against Xerox Corp. It requires Xerox to license its copier duplicator patents and also to make certain know-how available to competitors manufacturing in the United States. In other electronic applications selenium is used in semiconductors, photoelectric cells, and in calculators.

The largest single consumer of selenium continued to be the glass manufacturing industry. Selenium is added in amounts of 0.02 to 0.3 pound per ton of glass to neutralize the green iron discoloration. Dark-colored selenium-bearing environmental glass used in office windows to reduce glare and heat transfer, established itself as a growing energy conservation application.

In its major use in the industrial chemical field cadmium sulfoselenate compounds are used widely as heat-resistant red pigments in plastics, paints, inks, and enamels. Consumption of selenium in pharmaceutical preparations held steady at about 50,000 pounds in 1975.

Demand for selenium in other end uses included the addition of small amounts of ferroselenium to improve the casting, forging, and machining characteristics of stainless steel. There are also minor applications for elemental selenium and selenium diethyldithiocarbamate in the processing of natural and synthetic rubber. In 1975 an estimated 13,000 pounds of selenium contained in sodium selenite was added to premixed chicken, swine, and turkey grain feeds as a nutrient to control diseases and to increase production.

Stocks.—The drop in consumer demand for selenium led to a declining dealer price and a sharp increase in U.S. producer stocks. Stocks increased to 152,400 pounds at a level 93% higher than the yearend 1974 stocks. However, excluding the abnormally low inventories of 1974, the producer stock levels for 1975 were still below the average quarterly stocks of 174,000 pounds held between 1970–73. The Japanese selenium industry, the world's largest producer of selenium, held at least 300,000 pounds of refined material in producer inventories at the end of 1975, despite a 15% increase in export shipments.

Prices.—Selenium is usually sold as commercial-grade powder containing 97% to 99.94% selenium, or as high-purity grade in pellets, sticks, and powder containing 99.95% to 99.99+% selenium are also available.

Domestic producer prices for commercial-grade and high-purity grades remained unchanged during the year at $18 and $21 to $22 per pound, respectively. In contrast, dealer prices for commercial-grade selenium more accurately reflected the weak demand pressures. Starting the year at $15.50 per pound, the dealer selenium price dropped steadily reaching a low quotation of $8.25 per pound in late August. By yearend, dealer prices were quoted in the $9 to $10 range.

Foreign Trade.—Selenium exports decreased 29% from 1974 to 117,596 pounds valued at $2,130,991, with an average value of $18.12 per pound. As shown in table 10, shipments to Canada (32%), the United Kingdom (25%), Poland (9%), and Sweden (9%) accounted for the major share of exports.

Selenium imports for consumption increased 6% to a record high level of 889,320 pounds while the value of imports decreased 3% from 1974 to $10,264,543. The average value of unwrought selenium metal imported during the year was $11.54 per pound and for selenium dioxide $13.54 per pound. Canada supplied 59% by quantity and 68% by value, Mexico, 11% and 3%, and Japan, 9% and 9% of all selenium imported.

U.S. import tariff schedule items 632.40, selenium metal, unwrought, other than alloys, and waste and scrap; 420.50, selenium dioxide; and 420.52, selenium salts were duty free at yearend. The duty on TSUS Item No. 420.54, other selenium compounds, was 5% ad valorem.

e Estimate. p Preliminary. r Revised.

[1] Insofar as possible data relate to refinery output only; thus countries that produce selenium contained in copper ores, copper concentrates, blister copper and/or refinery residues, but do not recover refined selenium are excluded to avoid double counting.

[2] In addition to the countries listed, the U.S.S.R., West Germany, and Zambia are known to produce refined selenium, but production is not reported and available information is inadequate for estimation of reliable output levels.

[3] Data represent production for Peko-Wallsend Ltd. only for years ending June 30 of that stated.

[4] Net exports (exports minus imports).

[5] Refinery output from all sources including imports and secondary sources.

[6] Recoverable selenium content of blister copper treated at domestic refineries, plus refined selenium from domestic primary material.

Australia.—The Tennant Creek gold, bismuth, and copper mines in Central Australia, operated by Peko-Wallsend Ltd., have been Australia's largest producer of gold, bismuth, and selenium since mid-1973. In the year ended in July 1975, two of the five operating mines, the Juno and the Warrego, produced 80,000 pounds of selenium, an increase of 43% over the previous year. The Juno mine which produced 51% of 1974–75 selenium, is nearly exhausted with less than 1 year of gold-bismuth reserves remaining containing an estimated 16,500 pounds of selenium. This unusual selenium mineralization occurs as a complex series of seleniferous bismuth sulfosalts associated with gold and copper in hydrothermally replaced magnetite-hematite within volcanic sediments.[22]

The Warrego mine has remaining reserves of 6 million tons of 2.1% copper, 0.212 troy ounce gold and 0.30% bismuth containing an estimated 1.8 million pounds of selenium. High costs and low metal prices, however, forced the cessation of copper mining and smelting in December 1974, and of the entire Tennant Creek operation in late 1975. The uncertainty of mining resuming in this area may seriously affect the future production level of selenium in Australia.

Belgium.—As part of a 5-year expansion program begun in 1974, Métallurgie Hoboken-Overpelt S.A./N.V., one of Europe's largest selenium producers, has announced plans to increase its selenium production capacity.

Canada.—Selenium production from primary raw materials has decreased since 1971 as an increasing amount of copper production from Canadian mines is derived from selenium-poor ores. The major selenium producers, Canadian Copper Refiners Ltd. (CCR) owned by Noranda Mines Ltd., and The International Nickel Co. of Canada, Ltd. have annual capacities of 500,000 pounds and 180,000 pounds of selenium, respectively. In 1975 shipments by producers amounted to 670,000 pounds valued at Can$10,515,000. In 1974 Canada consumed only 30,500 pounds of selenium domestically, 73% in glass manufacturing, and the remainder in steel and pharmaceutical uses. Hudson Bay Mining & Smelting Co. Ltd. reported recovery of 133,577 pounds of selenium from 31,643 tons of copper from the Flin Flon and Snow Lake mines refined at CCR. Hudson Bay estimated remaining reserves of selenium at 2 million pounds contained in 483,500 tons of copper.

Japan.—The output of selenium by the six Japanese producers increased 15% in 1975 to 919,318 pounds according to the Japan Mining Industry Association.[23] Mitsubishi Metal Corp. produced 42% of the total; Nippon Mining Co., Ltd. (25%); Mitsui Mining & Smelting Co., Ltd. (14%); and Sumitomo Metal Mining Co., Ltd. (12%). Domestic shipments decreased by 66% to 147,700 pounds compared with 438,700 pounds in 1974. Domestic shipments by end use were as follows in 1975: Rectifiers, 22%; glass, 27%; pigments, 18%; and miscellaneous, 33%. With internal consumption at very low levels, the producers increased exports 144% in 1975 to 590,800 pounds. In the past 2 years excess production has contributed 300,000 pounds of selenium to Japanese industry stocks.

Zambia.—Development plans called for the construction of a new precious metals refinery at Ndola to recover gold, silver, and selenium from copper tankhouse slimes and to be operational by 1976. Between 1968 and 1973 Zambia exported an average of 65,000 pounds per year of selenium contained in slimes to Europe for refining.

Technology.—The Second International Symposium on Organic Selenium and Tellurium Chemistry held in Lund, Sweden in August 1975, highlighted the success of continuing research into the essential nature of selenium in animal and human nutrition. For years thought of only as a highly toxic, possibly carcinogenic element, research now suggests that selenium may be one of the more essential and beneficial trace elements in the biological system. Selenium has been determined as the functioning part of an important enzyme, glutathione peroxidase, whose presence is indicated to help counteract certain metabolic diseases and some forms of cancer. Selenium is also known to serve as an antidote for arsenic, copper, and mercury toxicities. If future studies on man substantiate these early findings the demand for supplemental selenium in pharmaceutical and agricultural applications could increase substantially.

TELLURIUM [24]

Domestic tellurium production of 131,000 pounds in 1975 was 31% below that of 1974, and the smallest quantity since 1968. The primary producers shipped 163,000 pounds of tellurium to consumers in 1975, an increase of 2% over 1974. Producer stocks decreased 37% to 55,200 pounds. The level of imports decreased 41% to 97,400 pounds from the record high of 164,000 pounds in 1974.

Table 13.—Salient tellurium statistics

(Thousand pounds of contained tellurium)

World: Production	320	396	446	r 447	328

r Revised.

Domestic Production.—Tellurium was recovered as a byproduct of electrolytic copper refining by: AMAX Copper, Inc., Carteret, N.J.; ASARCO Incorporated, Baltimore, Md.; and The Anaconda Company, Perth Amboy, N.J. Commercial-grade tellurium and tellurium dioxide was produced from the precious-metal-rich anode slimes shipped from other domestic copper refinery tankhouses. High-purity tellurium, tellurium master alloys, and tellurium compounds were produced by primary and intermediate processors from commercial-grade metal and tellurium dioxide. Lower production of tellurium in 1975 was attributed to reduced copper production and to the recession-generated drop in consumption, following the industry practice of adjusting production to meet the current demand. Construction of ASARCO's new copper and tellurium byproduct refinery in Amarillo, Tex., was on schedule and startup was expected in early 1976 at which time the Baltimore facility reportedly would be phased out. Anaconda closed its 77-year-old Perth Amboy refinery in April 1975, reducing the number of primary tellurium refineries in the United States to two.

Consumption and Uses.—Apparent consumption of tellurium for the year, as indicated by producer shipments to consumers and imports for consumption, decreased 20% from 1974 to 260,000 pounds. Tellurium consumption by end use in 1975 was estimated as follows: Iron and steel production, 70%; nonferrous metal production, 19%; chemical uses, 6%; and other uses including rubber manufacturing, 5%. Tellurium is used in its elemental state as a free-machining agent in stainless steel and copper production, in the chilling of malleable cast iron, and as a curing agent and accelerator in rubber compounding. Bismuth and lead telluride alloys are used in semiconductor and minor thermoelectric applications. Tellurium is used in the dioxide state in the forming and tinting of glass and as a chemical catalyst. Applications for tellurium are somewhat limited by the relatively small availability of refined material and by price. These factors make tellurium susceptible to substitution, particularly by lead in free-machining applications; lead exhibits many of the same properties as tellurium. Selenium and sulfur can substitute for tellurium in rubber compounding and germanium or selenium also substitute in some semiconductor applications.

Stocks.—Producers stocks decreased 32,000 pounds to an historically low level of 55,000 pounds. In addition to inventories of refined tellurium, there are available stockpiles of crude materials and impure intermediate tellurium products which are accumulated for refining as needed. There is no tellurium in the U.S. Government stockpile.

Prices.—The U.S. producer price for commercial-grade tellurium was $9 per pound from January to mid-September 1975. On September 19 the U.S. producers increased the price to the Canadian producers level of $10 per pound, and maintained it at that level through the end of the year.

---

[24] Prepared by George J. Coakley, physical scientist.

Tellurium is usually marketed in the form of minus 200-mesh powder or as slabs, tablets, or sticks. Normal commercial grades contain a minimum of 99% or 99.5% tellurium. Further refining through distillation and sublimation processes produces high-purity grades chiefly for use in semiconductors containing 99.95%, 99.999%, and 99.9999% tellurium.

Foreign Trade.—Tellurium metal imports decreased 42% in 1975 to 94,745 pounds valued at $926,392, with an average delivered value of $9.78 per pound. Canada with 33% and Peru with 63% supplied the major share of imports. In addition, 43,255 pounds of tellurium salts and 2,605 pounds of tellurium in compounds were also imported.

The U.S. tariff for 1975 on TSUS Item No. 632.48, tellurium metal, unwrought, other than alloys, and waste and scrap was 4% ad valorem and TSUS Items No. 421.90, tellurium compounds and 427.12, tellurium salts was 5% ad valorem. The duty on waste and scrap has been suspended until June 30, 1976. The statutory tariff on these items was 25% ad valorem. There are no data on tellurium exports.

Table 14.—U.S. imports for consumption of tellurium in 1975, by country

Country	Quantity (pounds)	Value
Unwrought, and waste and scrap:		
Belgium-Luxembourg	2,704	$22,284
Canada	31,621	316,489
Germany, West	1	634
Japan	220	1,801
Peru	59,354	579,061
United Kingdom	845	6,123
Total	94,745	926,392
Salts: Switzerland	43,255	186,139
Compounds:		
Canada	2,582	22,244
Germany, West	18	981
United Kingdom	5	294
Total	2,605	23,519
Grand total	140,605	1,136,050

World Review.—The United States continued as the world's largest producer and consumer of tellurium. In 1975, the United States produced 40% of all new refined tellurium while the U.S. apparent consumption was 79% of total world production of 328,000 pounds. The balance of world tellurium output in 1975 was distributed among Canada, Japan, and Peru.

Table 15.—Tellurium: World refinery production by country[1]
(Thousand pounds)

Country[2]	1973	1974	1975[p]
Canada	[3] 93	[3] 119	[4] 80
Japan	54	57	47
Peru	58	80	[e] 70
United States	241	191	131
Total	446	447	328

[e] Estimate. [p] Preliminary.

[1] Insofar as possible data relate to refinery output only; thus countries that produce tellurium contained in copper ores, copper concentrates, blister copper and/or refinery residues, but do not recover refined tellurium are excluded to avoid double counting.

[2] In addition to the countries listed, Australia, Belgium, Fiji, West Germany, and the U.S.S.R. are known to produce refined tellurium, and other major copper refining nations such as Chile, Zaire, and Zambia may produce refined tellurium, but production is not reported and available information is inadequate for estimation of reliable output levels.

[3] Refinery output from all sources, including imports and secondary sources.

[4] Recoverable tellurium content of blister copper, not necessarily recovered in year designated, plus refined tellurium from domestic primary metal.

Technology.—The Emperor Gold Mining Co., Ltd., Fiji, is now producing at a rate of 7,200 pounds of tellurium per year using the first new process capable of extracting tellurium economically from gold ores. The process involved the selective flotation of the crushed ore to produce a tellurium concentrate with the gold going off in the rougher tails. The tellurium concentrates are then oxidized in a soda ash circuit followed by cyanidation, filtering, and washing to remove any remaining soluble gold. The filter cake at this stage is then leached with sodium sulfide and filtered prior to the addition of sodium sulfite to precipitate high-purity tellurium.[25]

THALLIUM [26]

Thallium is a rare, highly toxic metal that is produced and used in small quantities in a restricted market.

Domestic Production.—The only domestic production of thallium and its compounds was the Globe plant of ASARCO, Inc. at Denver, Colo. Thallium is recovered as a byproduct derived from residues of base metal ore refining, principally zinc. Production of compounds in 1975 was only 27% of that in 1974; no thallium metal was produced. Shipments of metal increased 71% while compound shipments decreased 8%.

Uses.—The United States consumes a small fraction of the total world production of thallium. Prior to 1972, the principal use of thallium was as a rodenticide. The current uses for thallium include low-melting alloys, low-temperature thermometers and mercury switches, additives for altering the refractive index of glass, high-density liquids for sink-float separation of minerals, photosensitive devices, infrared light transmission devices, and as an additive to mercury lamps.

Prices.—The price of thallium in 25-pound lots has been $7.50 per pound since the end of 1957.

Foreign Trade.—U.S. imports for consumption in 1975 were 927 pounds of unwrought thallium and waste and scrap valued at $4,773, and 385 pounds of compounds valued at $8,636. The amount of imported metal was 9% less than in 1974. Imports accounted for most of the material entering commerce.

Table 16.—U.S. imports for consumption of thallium in 1975, by country

Country of origin	Compounds (gross weight)		Unwrought and waste and scrap	
	Quantity (pounds)	Value	Quantity (pounds)	Value
Belgium-Luxembourg	145	$3,094	45	$2,442
Germany, West	240	5,542	--	--
U.S.S.R	--	--	882	2.331
Total	385	8,636	927	4,773

World Review.—World mine production of thallium was estimated at 30,000 pounds. In addition to the United States, Belgium, West Germany, and the U.S.S.R. produced refined thallium.

World Reserves.—Domestic and world reserves of thallium in zinc ores were estimated to be 150,000 and 640,000 pounds, respectively. Other world resources of thallium contained in known zinc districts were estimated at 750,000 pounds.

Technology.—An artificial isotope of thallium, thallium-201, was used in a procedure to determine heart damage in heart attack victims. This isotope, because it preferentially concentrates in the heart tissue, is injected into the bloodstream and later viewed from outside the body with a scintillation camera; damaged heart tissue appears as light spots in the image. Thallium-201 can also be used in preventive medicine where it indicates areas of the heart which are receiving an inadequate blood supply. The thallium tracer method eliminates the potential danger of catheter scanning devices.[27]

The only discrete thallium mineral, carlinite (Tl_2S) was discovered at the Carlin gold mine in Nevada. The black carlinite crystals are randomly scattered through black brecciated fragments of a carbonaceous, high-thallium, low-arsenic, silicified limestone. The thallium, along with carbonaceous material, was thought to be leached from the limestone during the hydrothermal event which formed the Carlin gold deposits.[28]

GREENSAND [1]

Greensand, which is widely distributed in the Eastern United States, was produced in 1975 only by Inversand Co., a subsidiary of Hungerford & Terry, Inc., near Clayton, N.J. Production and sales information are not available for publication.

Raw greensand produced by the company was sold for agricultural use as a soil conditioner. Processed greensand was used by manufacturers as filter media in equipment for the removal of manganese, iron and other elements from water.

The University of Delaware received a grant of $17,051 from the Bureau of Mines early in 1976 to continue its studies of the effectiveness of greensand in removing metallic contaminants from waste waters.

IODINE [2]

The world iodine picture continued to vacillate in 1975, changing from short supply at the beginning of the year to a surplus condition at yearend. Prices maintained an even keel, ending the year at $2.59 per pound. U.S. imports during 1975 were considerably lower than in the record year of 1974, owing principally to the recession. There was a moderate reduction in stocks, which were artificially high at the beginning of the year because of a forecasted long-term shortage that was mostly discounted later. Domestic production continued to be quite small compared with imports and total consumption. The Dow Chemical Co., the only U.S. producer, maintained its small output at almost 1974 levels. However, the joint venture of Pittsburgh Plate Glass Co. (PPG) and Amoco Oil Co. to exploit the iodine brines near Woodward, Okla., is moving ahead on schedule and will be onstream in the first quarter of 1977. This will make an appreciable contribution to the U.S. supply. In addition, at least one other company has definite plans to exploit brines in adjacent areas in the near future.

Japan, the major iodine producer of the world, appears to have solved its production problems and indeed may have increased its reserves and sustained production capability at least for the near term. Production rose 3% in 1975 but was still 9% lower than the record 16.5 million pounds produced in 1972. Chilean iodine production continued at a moderate level of 4.3 million pounds in 1975; exports to the United States were of minor consequence.

Legislation and Government Programs.—

---

[1] Prepared by William F. Keyes, physical scientist.
[2] Prepared by J. W. Pressler, physical scientist.

On December 31, 1975, the Government strategic stockpile contained 8,011,814 pounds, the same as a year earlier. The stockpile objective for iodine had been reduced to zero in early 1973. However, congressional approval to dispose of the excess iodine had not been obtained by yearend.

The depletion allowance for iodine remained at 14% of gross income, and was not to exceed 50% of net income without the depletion deduction.

Domestic Production.—Dow Chemical recovered crude iodine from well brines at its Midland, Mich., plant, as a coproduct with bromine, calcium and magnesium compounds, and potash by its standard two-step process.

Consumption and Uses.—Based upon a Bureau of Mines canvass, approximately 4.4 million pounds of crude iodine was consumed by 31 plants in 14 States. Leading iodine-consuming States in 1975, in descending order of magnitude, were Missouri, New York, Pennsylvania, and New Jersey, which together accounted for more than two-thirds of the total crude iodine consumption.

About 2.2 million pounds of iodine went into organic compounds, 730,000 pounds into potassium iodide, 633,000 pounds into resublimed iodine, and 845,000 pounds into various other inorganic compounds. Possibly an additional 1 million pounds may have gone into other intermediates, mainly for catalytic use. It is expected that this catalytic use will outpace the other categories of iodine's use and be somewhat related to output of the automotive tire industry.

The annual canvass of the industry for consumption information is indicative of the pattern, but because of proprietary end uses, it is difficult to establish an accurate demand pattern by use. Again in 1975, imports alone were more than reported consumption, with a net difference of 909,000 pounds. Estimated consumption of iodine in the United States probably was close to 6.2 million pounds in 1975.

Table 1.—Crude iodine consumed in the United States

Products	1974			1975		
	Number of Plants	Consumption		Number of Plants	Consumption	
		Thousand pounds	Percent of total		Thousand pounds	Percent of total
Resublimed iodine	6	544	9	6	633	14
Potassium iodide	32	1,918	32	9	730	17
Other inorganic compounds	21	1,096	18	15	845	19
Organic compounds	23	2,517	41	21	2,193	50
Total	[1] 33	6,075	100	[1] 31	[2] 4,400	100

[1] Nonadditive total because some plants produce more than one product.

[2] Data do not add to total shown because of independent rounding.

A linear regression analysis of the Bureau-reported consumption of crude iodine in the manufacture of first downstream products indicated a 20-year (1956–75) historical-trend growth rate of slightly under 3%. In 1975, consumption of resublimed iodine increased 16% compared with 1974, and followed the latest 5-year growth rate trend of 11% per year. Total inorganics decreased 38% in 1975 compared with the previous year. Total organics decreased 13% in 1975, but the latest 5-year growth rate trend was over 5%.

In 1975, the major downstream uses were divided into the following categories: Catalysts for synthetic rubber, animal and fowl food supplements (mainly for cattle), stabilizers (as in nylon precursors), inks and colorants, pharmaceuticals, and sanitary uses. Iodine was also consumed in the making of high-purity metals, motor fuels, iodized salt, photo chemicals, smog inhibitors, lubricants, and many small uses, including cloud seeding. The use of iodine compounds as radio-opaque diagnostic agents in medicine is a minor but important application.

Prices.—Although the quoted price in 1975 was $2.59 per pound of crude iodine, prices were soft by yearend with some discounting in effect. Reflecting this, the average price for all of the iodine exported from Japan, which controls the bulk of the world iodine trade, was $2.28

per pound in 1975. However, this was a 22% increase over the average 1974 price of $1.87. U.S. demand did not live up to the expectation at the beginning of the year and moderated to influence both price and inventories. The quoted U.S. prices for iodine and iodine compounds at yearend 1975 follow:

	Per pound
Crude iodine, drums	$2.59
Resublimed iodine, U.S.P., granular, 100-pound drums, f.o.b. works	$4.00–5.25
Calcium iodate, drums, delivered	3.32
Calcium iodide, 35-pound drums, f.o.b. works	5.98
Potassium iodide, U.S.P., granular, crystals, drums, 1,000-pound lots, delivered	3.76
Sodium iodide, U.S.P., crystals, 300- to 500-pound lots, drums, freight equalized	5.16
Iodoform, N.F., drums, 300-pound lots, f.o.b. works	7.75–14.30

Source: Chemical Marketing Reporter, Dec. 29, 1975.

Foreign Trade.—Crude iodine imported into the United States in 1975 decreased 33% in quantity compared with 1974, and total value decreased 21%. The average value of imported crude iodine rose from $1.86 per pound in 1974 to $2.21 in 1975. Of the 5.3 million pounds of crude iodine imported, 93% was from Japan and 7% was from Chile. In a surplus, price-discounted situation, Chilean iodine did not find the ready market in the United States that it traditionally enjoyed prior to 1972. Imports of other iodine compounds, including resublimed iodine, were insignificant compared with imports of crude iodine.

Tariff rates were 8 cents per pound on resublimed iodine and 12 cents per pound on potassium iodide, with crude iodine entering the United States duty free.

Table 2.—U.S. imports for consumption of crude iodine, by country
(Thousand pounds and thousand dollars)

Country	1973		1974		1975	
	Quantity	Value	Quantity	Value	Quantity	Value
Chile	88	160	1,505	2,972	365	856
Japan	6,061	10,425	6,465	11,877	4,944	10,865
Total	6,149	10,585	7,970	14,849	5,309	11,721

World Review.—*Chile.*—Production of crude iodine in 1975 dropped 14% to 4.3 million pounds, compared with a reported 5.0 million pounds in 1974. Chile's production of crude iodine is associated with the production of natural potassium and sodium nitrates, which decreased 5.6% and 1.2%, respectively.

Nitrates and its associated iodine production earned Chile over $47 million ($5 million from iodine alone), and was the third most important mineral export. The State-owned corporation Sociedad Química y Minera de Chile S.A. (SOQUIMICH) produced all of the reported nitrates and iodine from the three mines and plants.

Because the price was initially pegged in 1975 at a level higher than farmers were willing to pay, Chile's domestic sales of nitrates suffered. Eventually the Chilean Government provided a special credit to farmers for nitrate purchases, unfortunately too late in the growing season to be of much help. The decline in export receipts in 1975 versus 1974 (from $54 million to $42 million), however, is due more to fall-off in volume than price. After running a $25 million deficit in 1975, SOQUIMICH is abandoning all investment projects that would lead to increased production and is retaining only those that will reduce costs. Production and sales are dropping markedly, but the industry is beginning to operate without the need for subsidies.

Chile did not regain any of its iodine export market to the United States in 1975; the U.S. Bureau of the Census reported only 365,000 pounds was imported, a 76% decrease from 1974 figures.

China, People's Republic of.—China's iodine production appeared to be balanced, importing only token amounts from Japan and Chile. Imports from Japan were 22,000 pounds in 1975, the same as 1974. No figures are available for Chile's 1975 iodine exports to China, but they were probably of minor significance.

Indonesia.—Ise Chemical Industries, Ltd's joint venture with Mitsui & Co. Ltd., and the Indonesian Government will have a capacity of 600,000 pounds of iodine per year when completed. Indonesia produced 73,000 pounds of crude iodine in 1975, a 28% increase over 1974 production.

Japan.—Japan continued to dominate the world iodine picture during 1975. Its output of 15 million pounds of crude iodine was a slight increase (2.5%) over 1974 but a decline of 9% from the record of 1972. The United States imported 4.9 million pounds of crude iodine from Japan in 1975, amounting to 33% of Japan's total iodine exports. Japan's production exceeded exports by 3.7 million pounds in 1975 and indicated a buildup of inventories due to the softer market at yearend. Japan's other important iodine export markets included the European Community countries, Switzerland, India, the U.S.S.R., and Canada, the same as in 1974.

During 1975, Ise Chemical Industries, Ltd.'s position in iodine production became more dominant, with all new plant construction in Japan being undertaken by them. In 1976 Ise was to complete a new 2.6 million-pound-per-year plant at Miyazaki, Kyushu, and a new 4 million-pound-per-year plant at Kurosaki.

It is reliably reported that the level of Japan's output of crude iodine may approach 18 million pounds per year by 1977, with the series of new plants and plant expansions now in progress. Chiba Prefecture is having new and greater development consideration, as the gas needs are now considered more important than the ground subsidence and environmental problems of recent times. The new Miyazaki area iodine reserves are very large and comparable to the reserves elsewhere in Japan.

U.S.S.R.—Soviet iodine production capacity was reported as 3.8 million pounds per year. Plants were operated at a high percentage of capacity. During 1975, Japan exported 396,000 pounds to the U.S.S.R., compared with 198,000 pounds in 1974.

MEERSCHAUM [3]

For the first time since 1972 crude meerschaum was imported for domestic consumption in 1975 and totaled 11,263 pounds in quantity and $20,337 in value. For comparison, imported meerschaum in 1972 totaled 11,139 pounds valued at $22,791. The principal source of imports in 1975 was the Somali Republic (99.8%).

QUARTZ CRYSTAL [4]

Cultured quartz crystal production increased 37% from 528,664 pounds in 1974 to 724,343 pounds in 1975. Consumption of cultured quartz increased, while consumption of natural quartz dropped for the first time since 1971. Exports of natural and cultured quartz increased significantly in 1975. Production of finished piezoelectric units increased 11% to 39,545,000 units.

Legislation and Government Programs.—The stockpile objective for electronic-grade quartz crystal remained at 209,000 pounds. As of December 31, 1975, the Defense Materials Inventory was 2,717,978 pounds, which included predominantly stockpile-grade material. Sales of stockpile excesses totaled 335,117 pounds in 1975.

Domestic Production.—The publication Arkansas Mineral Producers and Production 1975, prepared by the Arkansas Geological Commission, listed two operations as producers of quartz crystal: Ocus Stanley, Mt. Ida, Ark., and Terry Mining Corp., Midwest City, Okla. Total production for these two companies was listed as 29,840 pounds. The report gave no indication as to the quality or characteristics of the quartz crystals.

r Revised. NA Not available.

Seven companies reported production of cultured quartz for use by the quartz-crystal-cutting industry. These companies were P. R. Hoffman Co., Carlisle, Pa.; Motorola, Inc., Chicago, Ill.; Bliley Electric Co., Cortland, Ohio; Sawyer Research Products, Inc., Eastlake, Ohio; Thermodynamics Corp., Shawnee Mission, Kans.; Western Electric Co., Inc., North Andover, Mass.; and Electro Dynamics Corp., Shawnee Mission, Kans.

Cultured quartz production increased 37% to 724,343 pounds in 1975. Production was stimulated by the tremendous increase in popularity of citizen's band (CB) radios and electronic watches.

Sawyer Research Products, the leading producer of cultured quartz, twice announced expansion plans. The first announcement was for a 15% increase in capacity at an investment of $2.5 million. Later, an additional $2 million expansion program was announced, thereby increasing capacity by a total of 30%.

Consumption and Uses.—Consumption of raw (uncut natural or cultured crystal) quartz crystal increased 17% to 332,187 pounds in 1975. Consumption of cultured continued to dominate over that of natural quartz. Cultured quartz consumption increased 49% over the 1974 level. Natural quartz consumed declined 26% in 1975.

The 1975 production and consumption data were derived from reports received from 34 crystal-cutting operations in 17 States. Finished piezoelectric units were produced by 43 companies, of which 23 also had cutting operations. Of the total cutting operations, 21 cut cultured quartz only and 13 cut both natural and cultured quartz. None of the reporting companies cut natural crystal only. Illinois was the leading quartz-crystal-consuming State, followed by Pennsylvania, Kansas, and Massachusetts.

Piezoelectric units were manufactured in 17 States. Thirty plants in Kansas, Illinois, Florida, Pennsylvania, and California supplied 80% of the total output of finished crystal units. Oscillator plates comprised 75% of production. The remainder was used for filter plates, telephone resonator plates, and other items.

Reeves-Hoffman Division of Dynamics Corp. of America, a leading producer of quartz crystals for watches, announced plans for completion of a new plant by the end of 1976. The plant, which will produce AT crystals as well as watch crystal units, will double the company's manufacturing space and will be located in McConnellsburg, Pa.

Stocks.—Total stocks of raw quartz crystal (cultured and natural) increased 22% from 256,373 pounds in 1974 to 311,556 pounds in 1975. Of this total, 179,498 pounds was cultured quartz and 132,058 pounds was natural quartz.

Foreign Trade.—U.S. exports of natural quartz crystal almost doubled, from 165,837 pounds in 1974 to 313,330 pounds in 1975. Exports of cultured quartz increased 30% from 133,035 pounds in 1974 to 172,689 pounds in 1975. The average price per pound was $5.29 for natural quartz and $23.49 for cultured quartz.

DEPOSITORY

ERRATA

MINERALS YEARBOOK 1975

Volume I—Metals, Minerals, and Fuels

Page 1543 of the bound volume was misprinted. Please insert attached correct page.

Lime.—Consumption of lime in New Jersey declined 5% from 119,200 tons in 1974, to 113,313 tons in 1975. There was no production of lime in New Jersey in 1975.

Magnesium Compounds.—Production of magnesium compounds decreased 32% compared with 1974 with a 31% increase in average unit value. Refractory magnesia was produced in Cape May County from dolomite and domestic seawater.

Marl, Greensand.—Greensand, which is widely distributed in the eastern United States, was produced in 1975 only by the Inversand Co., a subsidiary of Hungerford and Terry Inc., near Clayton. Raw greensand produced was sold to Zook and Tanck, of Gap, Pa., for agricultural use as a soil conditioner. Processed greensand was used by manufacturers as filter media in equipment for the removal of manganese, iron, and other elements from water.

Perlite.—Crude perlite mined in Colorado, Nevada, and New Mexico was expanded at two plants in Middlesex County and used in roof insulation, plaster and concrete aggregate, masonry and cavity filler, and as a soil conditioner.

Sand and Gravel.—The total output of sand and gravel decreased 27% in quantity and 16% in value from that of 1974. Production of sand and gravel for construction declined 30% in quantity and 27% in value compared with 1974. Average value per ton was $2.04 in 1975. Of the 10.3 million tons of sand and gravel used for construction, 57% was processed sand, 28% was processed gravel, and 15% was unprocessed sand and gravel. Output of industrial sand decreased 16% in quantity and 5% in value with an average unit value of $5.98 per ton. Industrial sand accounted for 21% of the tonnage and 41% of the value of all sand and gravel produced in the State. The primary uses of industrial sand were for glass, molding, and foundry purposes. Most of the industrial sand was produced in Cumberland County. Dredging operations were the principal method for recovery of the sand. The number of sand and gravel operations dropped by 16 to 73. Production came from 14 of the State's 21 counties. The leading producing counties, ranked by tonnage, were Cumberland, Burlington, Ocean, Morris, and Middlesex. Cumberland County ranked first in value.

Table 5.—New Jersey: Construction and industrial sand and gravel sold or used by producers

(Thousand short tons and thousand dollars)

Use	1974		1975	
	Quantity	Value [1]	Quantity	Value [1]
Construction:				
Processed:				
Sand	8,309	15,588	5,901	11,840
Gravel	4,122	11,226	2,847	7,786
Unprocessed:

Industrial:				
Sand	3,247	17,272	2,730	16,321
Gravel	--	--	W	W
Total [2]	17,924	45,929	13,012	37,293

W Withheld to avoid disclosing individual company confidential data; included with "Construction."

[1] Value f.o.b. plant per ton of processed sand and per ton of processed gravel. Values in all other tables are f.o.b. plant for blended processed sand and gravel used as construction aggregate. Unit value of construction aggregate is generally higher than the unit value of unblended processed sand or gravel.

[2] Data may not add to totals shown because of independent rounding.

Imports of raw natural quartz crystal, valued at more than $0.50 per pound, increased from 388,677 pounds valued at $367,943 in 1974 to 584,647 pounds valued at $884,627 in 1975. This category includes both electronic-grade quartz and the lower quality material, lasca. Brazil was the source for 99% of this material. Imports of quartz valued at less than $0.50 per pound were 902,625 pounds valued at $46,111 in 1975. Brazil was the principal source of the category (91%) with Canada, the Netherlands, the United Kingdom, and West Germany providing the balance.

World Review.—*Brazil.*—Brazil continued as the principal world source for electronic-grade natural quartz and lasca for use by fused quartz and cultured quartz producers. Brazil announced an export quota for 1975 of 7.7 million pounds of lasca. The f.o.b. floor prices for lasca were $2.72 per pound of first-grade lasca, $1.59 per pound of second-grade lasca, and $0.76 per pound of third-grade lasca. The criteria for quota distribution included consideration of price and exporters and importers traditional experience in dealing with Brazilian companies.

United Kingdom.—Cultured quartz for use in various piezoelectric units was produced by two companies in the United Kingdom: Solford Electrical Instruments Ltd., a division of U.K. General Electric Co., and Standard Telephones and Cables Co. Ltd. Both companies produce cultured quartz for internal use only. Both grow the quartz using hydrothermal synthesis. Annual production of cultured quartz is estimated to be 26,880 pounds.

Exports of cultured quartz are estimated to be 3,360 pounds; most is sent to overseas subsidiaries of Standard Telephones and Cables Co. Sources of lasca (quartz feedstock) include Brazil, India, Africa, and the United States.

Japan.—Five firms produced cultured quartz in Japan: Toyo Communication Equipment Co., Ltd.; Kinsekisha Laboratories, Ltd.; Nippon Dempa Electro Instruments Co., Ltd.; Meidensha Electric Manufacturing Co., Ltd.; and Daiwa Shinku Kogyosho. Estimates of the production of the hydrothermally grown quartz range between 24,255 and 44,100 pounds tons per month. Toyo Communication is the only exporter of cultured quartz. Lasca sources are Brazil and the United States.

Technology.—Use of newly developed devices to replace crystal units in CB and other radios could lead to a decline in the number of quartz crystals required for each radio. The digital or phase-locked-loop synthesizers use only a single master crystal to generate all of the channels rather than the current 12 to 14 crystals used in most CB radios.[5]

STAUROLITE [6]

Staurolite is a complex iron-aluminum silicate of uncertain and most likely variable composition. It occurs as opaque crystals that are reddish-brown to black, have a specific gravity of 3.65 to 3.77, and fall between quartz and topaz in hardness (7 to 8 on Moh's scale). Aside from a small rock-shop trade in cruciform-twinned crystals (notably from deposits in Georgia, North Carolina, and Virginia) that have been called "fairy crosses" and are sold as curios or amulets, all the staurolite produced commercially in the United States is a byproduct obtained by high-intensity magnetic separation of a heavy-mineral mixture recovered by E. I. du Pont de Nemours & Co., Inc., from beach sand in a glacial age deposit in Clay County, Fla.

Formerly the staurolite concentrate was used only as an ingredient in portland cement mixtures, but more recently this product (which may contain minor proportions of various other minerals and averages about 45% Al_2O_3, 15% Fe_2O_3, and 30% SiO_2) is being marketed by du Pont under two trade names, as Starblast for use as a sandblast abrasive, and Biasil for mixing with bentonite and other substances to prepare special-purpose foundry sand.

Quantitative production data are not released for publication, but the 1975 output of staurolite was 37% less than that of 1974, while shipments decreased 34% in tonnage and 10% in total value.

STRONTIUM [7]

Domestic consumption of strontium on a carbonate basis was estimated at 15,000 short tons in 1975, a 40% decrease from 1974 consumption. Imports of strontium minerals decreased 44% to 21,613 short tons. Imports of strontium chemicals, primarily from Canada, decreased 64%.

Legislation and Government Programs.—Government stockpiles contained 14,408 tons of non-stockpile-grade celestite at yearend. This material has been declared excess; however, authorizing legislation must be obtained before it is released for disposal.[8]

Domestic Production.—Strontium minerals have not been produced commercially in the United States since 1959. However, a number of firms produced strontium compounds from imported celestite.

Table 4.—Major producers of strontium compounds, 1975

Company	Location	Compounds
Atomergic Chemetals Co	Carle Place, N.Y	Various compounds.
J. T. Baker Chemical Co	Phillipsburg, N.J	Do.
Barium & Chemicals, Inc	Steubenville, Ohio	Do.
Chemical Products Corp	Cartersville, Ga	Carbonate.
FMC Corp	Modesto, Calif	Carbonate, nitrate.
Hercules, Inc	Glens Falls, N.Y	Chromate.
King Laboratories, Inc	Syracuse, N.Y	Metal alloys.
Mallinckrodt Chemical Works	St. Louis, Mo	Various compounds.
Mineral Pigments Corp	Beltsville, Md	Chromate, molybdate.
NL Industries, Inc., Tam Div	South Amboy, N.J	Titanates.

Consumption and Uses.—Domestic consumption of celestite in the manufacture of various strontium chemicals appears to have stabilized in 1975 even though carbonate from Canada was available in large quantities. Although quantitative information concerning consumption is incomplete, sales of domestically produced strontium carbonate to manufacturers of glass for color television picture tubes declined. Celestite consumption for the manufacture of pyrotechnics appeared to have been stabilized.

Miscellaneous applications for strontium compounds included ferrites, greases, ceramics, plastics, toothpaste, pharmaceuticals, paint, electronic components, welding fluxes, and high-purity zinc. Small quantities of strontium metal were produced by research companies.

Prices.—At yearend, prices quoted in Chemical Marketing Reporter were as follows: Strontium carbonate, technical—bags, carlots, works, 18 cents per pound; strontium nitrate—bags, carlots, works, $24 per 100 pounds, up $3 from 1974. Prices for strontium minerals are usually determined by direct negotiations between buyer and seller and are seldom published. The average value of imported strontium minerals at foreign ports was $38 per short ton, up $8 from 1974.

Foreign Trade.—Imports of strontium minerals totaled 21,613 tons, a 44% decrease from 1974. The material was imported from Mexico and Spain. Imports of strontium compounds decreased 64% from those of 1974 with 98% of the material coming from Canada. Quantitative data on U.S. exports of strontium compounds were not available.

[e] Estimate. [p] Preliminary.

[1] In addition to the countries listed, West Germany, Poland, and the U.S.S.R. produce strontium minerals, but output is not reported quantitatively, and available information is inadequate to permit formulation of reliable estimates of output levels.

[2] Year beginning March 21 of that stated.

Technology.—Research sponsored by the U.S. Energy Research and Development Administration under contract with Union Carbide Corp. resulted in a high-efficiency thermochemical cycle for the decomposition of water. The cycle is based on reactions of chromium and strontium compounds. Temperatures required have already been exceeded in high-temperature gas-cooled nuclear reactors; 100% yield was obtained below 800°C. There are no difficult gas separation problems. The cycle is a potential source of hydrogen for synthetic and for fuel uses.[9]

WOLLASTONITE[10]

Wollastonite is a naturally occurring calcium metasilicate, usually white or light colored and sometimes acicular to silky-fibrous in structure, with the theoretical composition of $CaO \cdot SiO_2$, equivalent to 48.3% CaO and 51.7% SiO_2. The mineral, used as a ceramic raw material, as a filler for plastics and asphalt products, as a pigment and extender for paints, and in miscellaneous minor applications, was mined in the United States in 1975 only by Interpace Corp. at an underground operation in Essex County, N.Y. Specific output data were not released for publication, but the tonnage produced in 1975 was 14% less than in 1974, while the reported total value was 2% higher. An article published in an industrial magazine that presented a review of the world situation, historical and current, with regard to wollastonite production and utilization, stated that present U.S. output of the mineral is estimated to be 66,000 to 77,000 tons per year.[11]

Production of wollastonite outside the United States in 1975 was reported in Finland, 14,430 tons (flotation concentrate); Turkey, 11,350 tons; India, 1,045 tons; and Mexico, 600 tons.

Chemical Marketing Reporter, December 29, 1975, quoted the price of wollastonite, fine paint grade, bagged, in carload lots, f.o.b. works, as $43.80 per ton; medium paint grade, $33.00 per ton. The December 29, 1975, issue of American Paint & Coatings Journal quoted prices ranging from $29.00 to $50.50 per ton for paint-grade wollastonite. The price range quoted in the December 1975 issue of Industrial Minerals (London) for wollastonite (imported, ground, bagged, c.i.f. main European port) was approximately equivalent to $107 to $132 per short ton.

ZEOLITES[12]

The Federal Bureau of Mines, the U.S. Geological Survey, the National Science Foundation, the American Chemical Society, 18 industrial organizations, the Mineralogical Society of America, the Clay Minerals Society, and the Society of Economic Geologists cooperated in conducting an international conference on natural zeolites in 1976. The 1975 edition of a primary reference book[13] included a chapter devoted to these minerals. These developments indicate the growth of interest in zeolites in the technical, industrial, and academic communities.

The Bureau of Mines has done a limited amount of research[14] on zeolites and is accumulating information on development of markets and production capacity. An adequate data base is not yet available from which to make firm economic assessments, but the potential utility of these minerals is so great that a review of the known data is being included in the Minerals Yearbook.

According to Breck,[15] zeolites are natural or synthesized, crystalline, hydrated aluminosilicates of Group I and Group II elements, particularly sodium, potassium, magnesium, calcium, strontium, and barium. There are 34 zeolite mineral species and about 100 types of synthetic zeolites, but only a few currently have practical significance. Structurally, they are framework aluminosilicates, and to be used as a molecular sieve the zeolite structure must remain intact after complete dehydration.

Domestic Production.—There is no sustained production of natural zeolites in the United States. Several companies have mined and sold several thousand tons of these minerals over the last few years, but this has been mainly on an "as ordered" basis.

Several companies with proven ore bodies have done at least the basic planning to be ready to react to market demand. A few of the ore bodies have had the overburden removed, and some even have stockpiles of mined zeolites ready for shipment. At least one company has mined, processed, and pelletized natural zeolites in stock.

Zeolites that are manufactured by synthesis from various raw materials may be categorized into two groups; the pure zeolites and zeolite-containing catalysts. There is an area of overlap when the pure zeolites are used as catalyst carriers or support for other active ingredients, but these will be treated only as the pure zeolites and designated "synthetic zeolites." The "zeolitic catalysts" will have that designation and will be treated separately because they usually contain zeolites in a host matrix. The zeolite content of Mobil Oil Corp.'s Durabead 5 cat-cracking catalyst was 25% in a silica-alumina matrix, but the average zeolite content seems to be about 10%.

There is no finite production data available on synthetic zeolites, but one manufacturer estimated 1974 production at 4,000 tons and an annual growth rate of 10% to 12%. The average 1972 price was $2,000 per ton.

Production data on zeolitic catalysts of necessity will remain less than finite; much of the basic research is done by the using oil companies, and the manufacturing is done under secrecy agreements with the synthesizer. The producers say that the zeolite content of the 130,000 tons of cracking catalysts used annually is about 10%, or 13,000 tons. The 126,000 tons used in 1972 was worth $66 million.

Consumption and Uses.—*Natural Zeolites.*—There are at least five market areas where zeolites are being used commercially in the United States. The first such use was unrecognized until comparatively recent years, when it was discovered that various zeolites were major constituents of the pozzolans in pozzolanic cement. Analcime, chabazite, and clinoptilolite are the varieties identified so far in European pozzolans and occur in amounts of 20% to 80% of the constituent minerals. A clinoptilolite-rich tuff near Tehachapi, Calif., was the source of the pozzolan for Monolith Portland Cement Co. for many years.

The second, and fastest developing market at present relates to the specificity of clinoptilolite for removal of the ammonia ion (NH_3) from sewage waters. This was first demonstrated by Mercer[16] in 1970 with a mobile unit at Lake Tahoe, Calif., in which 97% of the entrained ammonia was removed from sewage waters. A 600,000-gallon-per-day (gpd) plant at Minneapolis-St. Paul, Minn., using 90 tons of clinoptilolite went onstream in early 1974. Two Virginia plants, one a 10-million-gpd unit at Reston using 1,800 tons of clinoptilolite and the other a 54-million-gpd unit at Alexandria, will be onstream shortly. Attrition and replacement rates for zeolites in this use are not known, but full replacement is not expected to be needed for 5 to 10 years.

The third commercial use at present is in the field of drying and purification of acidic natural gases. The chabazite-erionite zeolites from the Bowie, Ariz., deposit have proved their ability to remove water and carbon dioxide from sour gases, and 130 tons were sold between 1970 and 1972 from the Bowie deposit of Union Carbide Corp.

The fourth area of current usage is a good example of the creation of new technology to solve an environmental problem and recover a valuable product at the same time. The NRG Corp. developed and has onstream a zeolite-adsorption process for purifying the methane gas produced by bacterial action on garbage in a sanitary landfill. The first unit is delivering pipeline-quality methane to the local gas company from a plant at Palos Verdes, Calif., and is expected to be followed by many more.

---

[16] Mercer, B. W., and others. Ammonia Removal From Secondary Effluents by Selective Ion Exchange. Water Pollution Control Federation J., V. 42, 1970, pp. R95–R107.

The fifth use, as dimension stone, is another area of longtime but unrecognized use. Zeolite tuffs, because of the ease of quarrying and relative light weight of the stone, have been a source of building material for at least 2,000 years. The Mayas of southern Mexico used this material as did the builders of Naples, Italy, and even some early ranchers in the Western United States. An erionite-rich tuff near Rome, Oreg., is still being quarried for a few hundred tons of facing stone each year.

Preliminary research has indicated a great agricultural potential for zeolites in such diverse areas as soil stabilization, slow release encapsulants for pesticides and nutrients, animal feeding, and deodorant for animal wastes.

Other uses abroad that have not yet entered the U.S. market and the potential uses indicated by ongoing research are covered under Technology.

Synthetic Zeolites.—Synthetic zeolites have a large, expanding, diverse market that often changes by new applications generated in the research laboratories of producers. In 1974, the major market areas were using zeolites for their selective adsorption capabilities as dessicants, gas stream cleaners, vapor adsorbers, etc. The chemical and petroleum industries were using 42% of synthetic zeolites produced, natural gas processing 22%, refining 10%, refrigeration and insulating glass 8% each, industrial gas 2%, and others 8%.

Zeolites have some catalytic effect of their own, are a part of the cat cracking catalyst of choice, and make good support material for other catalytically active agents. In 1974, zeolitic catalysts had 92% of the total cracking catalyst market in the United States. This represented 126,600 tons of catalyst (about 10% zeolites) worth $66 million. Metallic catalysts on zeolite supports were an unknown part of the $12.8 million-per-year hydrocracking catalyst market.

Prices.—In 1974 the clinoptilolite used in the Rosemont, Minn., sewage treatment plant cost about $400 per ton. In that year synthetic zeolites were averaging $2,000 per ton, and cat-cracking zeolitic catalysts more than $500 per ton. In 1976 one company offered natural zeolites that had been "activated by heating" and pelletized at around $1,000 per ton in large bulk shipments.

Foreign Trade.—Trade data are lacking. Inquiries from Europe about availability of clinoptilolite and from South Korea about markets for mordenite presage future foreign trade in natural zeolites. However, aside from the very lively trade in laboratory specimens, the only discernable international trade at present seems to be the importation by Japan of mordenite and other South Korean types.

International trade in synthetic zeolites seems to have some limitations. There has been widespread distribution of laboratory amounts of U.S. products as attested by articles in the foreign literature telling of experimentation involving these zeolites. The low-density, high-bulk characteristics of these materials make for transportation difficulties. This industry seems to be exporting technology rather than product and is opening manufacturing plants abroad at an accelerated rate.

The zeolite catalyst international market seems assured. The complicated technology and highly secretive manufacturing methods for producing the cracking catalyst of choice seem to assure that product rather than technology will be exported. The United States will remain the main source of zeolitic catalysts for the oil refiners of the world.

World Review.—One author[17] estimates an annual worldwide production of 300,000 tons per year of natural zeolites from mines in the United States, Japan, Italy, Hungary, Yugoslavia, Bulgaria, Mexico, and Germany. Some of the large uses for these predate their identification as zeolites and will make tabulation of tonnages extremely difficult; these large uses are as pozzolans in cements and concrete, as lightweight aggregates, and as soil conditioners, for which there is evidence of centuries-old use by Japanese farmers.

Resources.—Available resources of zeolitic minerals will not be firmly quantified for many years; exploration is very active and new deposits are being found.

Tonnages cannot even be guessed at with the fragmentary knowledge now available, but the following countries apparently have deposits of sufficient grade to have economic potential: Argentina, Australia, Bulgaria, Canada, Chile, France, West Germany, Hungary, Italy, Japan, Mexico, New Zealand, the Republic of South Africa, South Korea, Tanzania, the U.S.S.R., the United States, and Yugoslavia.

---

[17] Work cited in footnote 13.

The nine zeolites that commonly make up the major portion of the zeolitic rocks in sedimentary beds are analcime, chabazite, clinoptilolite, erionite, ferrierite, heulandite, laumontite, mordenite, and phillipsite. The most abundant in sedimentary rocks are analcime and clinoptilolite. Some of these same zeolites occur in pyroclastic rocks in minable amounts. The reference work[18] previously cited states that if grade and depth of overburden restraints are ignored, the total identified, hypothetical, and speculative resources of zeolites in the United States are conservatively estimated at 10 trillion tons. In approximate order of decreasing abundance the common zeolites are clinoptilolite (including heulandite), analcime, mordenite, erionite, phillipsite, chabazite, laumontite, and ferrierite. The United States probably has the world's largest potential resources of high-grade chabazite, erionite, and phillipsite and the only high grade deposits of ferrierite in the world are reported in central Nevada.

Technology.—Zeolites are very likely the first group of abundantly available natural minerals whose exploitation will come after the establishment of a successful industry based on the synthesis of analogs and of 70 or 80 types not found in nature. Creation of new materials has led to much academic interest and to technological advances by such companies as Union Carbide Corp., Mobil Oil Corp., W. R. Grace & Co., Shell Oil Co., and Norton Co. The availability of the pure monotypical synthetics shortened laboratory time because results could be related to fewer variables and not confused by the effects from impurities and varying pore sizes.

No attempt will be made to divide the proven and potential applications of zeolites between the synthetic and natural because there is and probably always will be significant overlap. For example, pressure-swing-absorption processes utilizing synthetic zeolites have been patented, as has at least one process using natural zeolites to effect oxygen enrichment of air. These processes can produce up to 95% oxygen with most of the remainder argon, and are economically advantageous for plant sizes up to 25 tons per day.

Some of the characteristics of zeolites that make them useful are present in other minerals to varying degrees. The presence of several of these characteristics in a single mineral makes zeolites unique and valuable.

The term molecular sieve partially describes what is probably the most valuable characteristic of zeolites. Specifically, their cage structure makes them porous, and the different pore sizes and shapes of the various zeolites can selectively adsorb or reject different molecules. Use of this property made the air separation unit previously mentioned possible. Zeolites are being used as gas dryers and desiccants in many ways and as purifiers of gas streams.

Besides their purely physical adsorption characteristics, zeolites have unique properties not found in conventional adsorbents. They will selectively adsorb molecules with a permanent dipole moment and other interaction effects. They are valuable ion exchange agents and have types of selectivity for discrete cations not available elsewhere. This can be useful, as already proven, in the concentration and removal of radioactive strontium and cesium from the waste waters of nuclear facilities, for removing the ammonia (NH_3^-) ion from waste water treatment plant effluent, and also for altering the physical parameters and catalytic activity of the zeolites. As an example Linde's zeolite 4A is the sodium form of their zeolite A structure, which, when the sodium is exchanged for calcium, has an effective pore size 1 angstrom larger and becomes their zeolite 5A.

Research on zeolites has so far been concentrated on the synthetics. There are valid reasons for this, as previously mentioned, and there are also valid reasons why application and characterization research on the natural zeolites should be hastened. Economics is chief among these because there are many potential applications of great usefulness in the agricultural and environmental areas where the less expensive minerals can be used whereas the more expensive synthetics might never find a market.
